Stahl's method of procuring fulphurous acid was to burn fulphur at a low temperature, and expose to its flames cloth dipped in a folution of potals. By this method he obtained a combination of potals and fulphurous acid; for at a low temperature fulphur forms by combustion only sulphurous acid. On this salt Scheele poured a quantity of tartarous acid, and then applied a gentle heat. The fulphurous acid is in this manner difplaced, because its affinity for potals is not so strong as that of tartarous acid; and it comes over into the receiver diffolved in water. It is now commonly procured by mixing with fulphuric acid oil, greafe, metals, or any other substance that has a stronger affinity for oxygen than fulphurous acid, and applying a heat fufficient to distil over the sulphurous acid as it forms. Mr Berthollet has found, that fugar is the best substance to employ for this purpose.

Dr Priestley poured a little oil on sulphuric acid, applied heat, and received the product in a glass jar filled with mercury. It was fulphurous acid free from all

superfluous water, and in a gaseous form.

In this state it is colourless and invisible like common air. It is incapable of maintaining combustion; nor can animals breathe it without death. It has a ftrong and fuffocating odour. It is this odour which burning fulphur exhales. Its fpecific gravity, accord-

ing to Bergman, is 0,00246+; according to Lavoider, Sulphurous 0,00251 t Clouet and Monge found, that by the application of extreme cold it is converted into a liquid. + On Elec-

Water, SECT. III. Of Nitric Acid.

THERE are three different substances composed of azot and oxygen, nitric acid, nitrous acid, and nitrous gas. The first contains most oxygen; the last contains least.

Nitric acid feems to have been first obtained in a fe-Discovery parate state by Raymond Lully, who was born at Ma- of nitric as jorca in 1235. He procured it by diffilling a mixture cid. of nitre and clay. Basil Valentine, who lived in the 15th century, describes the process minutely, and calls the acid water of nitre. It was afterwards denominated aqua fortis and spirit of nitre. The name nitric acid was first given it in 1787 by the French chemists. Nitric acid is generally obtained in large manufacto-

408

& Scheele.

procuring the acid procured by this process is weak and impure. of nitre and one of fulphuric acid in a glass retort. This method was first used by Glauber. When obtained in this manner it contains some nitrous acid, which may be expelled by the application of a very gentle heat §.

> Nitric acid is one of the most important instruments of analysis which the chemist possesses; nor is it of inferior consequence when considered in a political or commercial view, as it forms one of the most effential ingredients of gunpowder. Its nature and composition accordingly have long occupied the attention of philosophers. We shall endeavour to trace the various steps by which its component parts were discovered.

Discovery of its component parts.

As nitre is often produced upon the surface of the earth, and never except in places which have a communication with atmospheric air, it was natural to suppose that air, or some part of the air, entered into the composition of nitric acid. Mayow having observed, that nitre and atmospherical air were both possessed of the property of giving a red colour to the blood, and that air was deprived of this property by combustion and respiration-concluded, that nitre contained that part of the air which supported combustion, and was necessary far

Dr Hales, by applying heat to nitric acid, and what he called Walton mineral, obtained a quantity of air posfessed of singular properties. When atmospherical air was let into the jar which contained it, a reddish turbid fume appeared, a quantity of air was absorbed, and the remainder became transparent again *. Dr Priestley discovered, that this air could only be obtained from nitric (u) acid; and therefore called it nitrous air. He found, that when this gas was mixed with oxygen gas, nitrous acid was reproduced. Here, then, we find, that oxygen is a part of the nitric acid, and consequently

that Mayow's affirmation is verified.

Dr Priestley, however, explained this fact in a different manner. According to him, nitrous gas is composed of nitrous acid and phlogiston. When oxygen is added, it separates this phlogiston, and the acid of course is precipitated. This hypothesis was adopted by Macquer and Fontana; and these three philosophers endeavoured to support it with their usual ingenuity. But there was one difficulty which they were unable to furmount. When the two gafes are mixed in proper proportions, almost the whole assumes the form of nitric acid; and the small residuum (the part), in all probability, or rather certainly, depends on some accidental impurity in the oxygen gas. What then becomes of the oxygen and phlogiston? Dr Priestley supposed that they formed carbonic acid gas: but Mr Cavendish proved, that when proper precautions are taken, no fuch acid appears t.

Dr Prieftley had procured his nitrous gas by diffolying Nat metals in nitric acid; during the folution of which a great deal of nitrous gas escapes. He supposed that Method of ries by diffilling a mixture of nitre (T) and clay; but nitrous gas contained phlogiston, because the metal was oxydated (and confequently, according to the then re-Chemists generally prepare it by distilling three parts ceived theory, must have lost phlogiston) during its formation. Mr Lavoisier proved, that this supposition was il-founded, by the following celebrated experiment 1. 1 Men To 945 grains of nitric acid (specific gr. 1,316) he Par. 17 added 1104 grains of mercury. During the folution P. O73 273,234 cubic inches of nitrous gas were produced. He then distilled the salt (oxyd of mercury), which had been formed to dryness. As soon as it became red hot it emitted oxygen gas, and continued to do fo till almost the whole of the mercury was revived: The quantity of oxygen emitted was 287,742 cubic inches. All that had happened, therefore, during the folution of the mercury, was the separation of the acid into two parts; nitrous gas, which flew off, and oxygen, which united with the metal (x).

> Mr Lavoisier concluded, therefore, that the whole of the nitrous gas was derived from the nitric acid; that nitric acid is composed of oxygen and nitrous gas; and that the proportions are nearly 64 parts by weight of

nitrous gas, and 36 of oxygen gas.

But there was one difficulty which Mr Lavoisier acknowledged he could not remove. The quantity of oxygen obtained by decomposing nitric acid was often much greater than what was necessary to saturate the nitrous gas. Mr De Morveau attempted to account for this; but without success f. Nitrous gas itself was f Engli evidently a compound; but the difficulty was to disco- Mabal ver the ingredients. Mr Lavoifier concluded, from an Nitrigue experiment made by decomposing nitre by means of charcoal, that it contained azot: and several of Dr. Priestley's experiments led to the fame result. But

what was the other ingredient?

Mr Cavendish had observed, while he was making experiments on the composition of water, that some nitric acid was formed during the combustion of oxygen and hydrogen gas, and that its quantity was increased by adding a little azot to the two gases before the explosion. Hence he concluded, that the formation of the acid was owing to the accidental presence of azotic gas. To verify this conjecture, he passed an electrical shock through a quantity of common air enclosed in a glass tube: the air was diminished, and some nitric acid formed. He repeated the experiment, by mixing together oxygen and azotic gas; and found, that when they bore a certain proportion to each other they were totally convertible into nitric acid. In one experiment, the proportion of azot to oxygen (in bulk) was as 416 to 914; in another, as 1920 to 4860 *.

These experiments were immediately repeated by Trans Messrs Van Marum and Van Trooftwyk, and with near-

ly the fame refult.

The most convenient method of performing them is the following: Take a glass tube, the diameter of

(T) Nitre is composed of nitric acid and potals.

(u) Or nitrous acid; for at the period of Dr Priestley's discovery (1772) they were not accurately distinguished.

(x) We have already mentioned, in a preceding note, that this experiment was first made by Mr Bayen. See Part I. chap. iii. of this Article.

Nitric

Acid.

which is about the fixth part of an inch, through the cork that shuts one end of which let a small metallic conductor pass with a ball at each end. Fill this tube with mercury, and plunge its open end into a bason of mercury: then put into it a mixture of 0,13 of azotic and 0,87 of oxygen gas, till it occupies three inches of the tube; and introduce a solution of potass till it fill half an inch more. Then, by means of the conductor, make electrical explosions (from a very powerful machine) to pass through the tube till the air is as much diminished as possible. Part of the potass will be found converted into nitre. Mr Cavendish actually faturated the potals with this acid. Mr Van Marum did not, though a good deal more gas had disappeared than in the experiments of Mr Cavendish. 'This difference evidently depends on the quantity of potass contained in a given weight of the solution. The solution which Mr Van Marum used was no doubt stronger than that which Mr Cavendish employed.

Dr Priestley had observed several years before these experiments were made, that atmospherical air was diminished by the electric spark, and that during the diminution the infusion of turnsole became red; but he concluded merely, that he had precipitated the acid of the air. Landriani, who thought, on the contrary, that carbonic acid gas was formed, enounced the alteration of lime-water by it as a proof of his opinion. It was to refute this notion that Mr Cavendish undertook his experiments. He has since that time repeated them

with the same success of.

It cannot be doubted, then, that nitric acid is composed of azot and oxygen; for the objections of Dr Priestley have been considered while we were treating of water. Confequently nitrous gas must also be composed of the fame ingredients. According to Lavoifier, nitric acid is composed of four parts, by weight,

of oxygen and one part of azot.

Nitric acid is liquid, colourless, and transparent; but the affinity between its component parts is fo weak, that the action of light is fufficient to drive off a part of its oxygen in the form of gas; and thus, by converting it partly into nitrous acid, to make it affirme a yellow colour. Its tafte is exceedingly acid and peculiar. It is very corrofive, and tinges the skin of a yellow colour, which does not disappear till the epidermis comes off.

It has a strong affinity for water, and has never yet been obtained except mixed with that liquid. When concentrated, it attracts moisture from the atmosphere, but not fo powerfully as fulphuric acid. It also produces heat when mixed with water, owing evidently to

the concentration of the water. gth The specific gravity of the strongest nitric acid that can the ent be procured is, according to Rouelle, 1,583; but at if rathe temperature of 60°, Mr Kirwan could not procure

it stronger than 1,5543.

Taking this acid for the standard, Mr Kirwan has calculated how much of it exists in nitric acid of inferior denfity. His determination may be feen in the following table, which was formed precisely in the same manner as that formerly given of the strength of fulphuric acid.

Now, how much water does nitric acid contain, the denfity of which is 1,5543?

Mr Kirwan dried a quantity of crystallized carbonat Quantity of foda in a red heat, and diffolved it in water, in fuch a of real acid proportion, that 367 grains of the folution contained contained to concen-50,05 of alkali. He faturated 367 grains of this fo-trated ni-lution with 147 grains of nitric acid, the specific gravity tric acid. of which was 1,2754, and which therefore, by the preceding table, contained 45,7 per cent. of acid standard. The earbonic acid driven off amounted to 14 grains. On adding 939 grains of water, the specific gravity of the folution, at the temperature of 58,5°, was 1,0401. By comparing this with a folution of nitrat of foda, of the same density, precisely in the manner described for-merly under sulphuric acid, he found, that the salt contained in it amounted to 16,901 of the whole. There

was an excess of acid of about two grains. The weight of the whole was 1439 grains: The quantity of falt, confequently, was $\frac{1439}{16,901} = 85,142$ grains. The quantity of alkali was 50.05-14=36.05. The quantity of itandard acid employed was 66.7. The whole of which amounted to 102,75 grains; but as only 85,142 grains entered into the composition of the falt, the remaining 17,608 must have been pure water mixed with the nitric acid. But if 66,7 of standard acid contain 17,608 of water, 100 parts of the same acid must contain

One hundred parts of standard nitric acid, therefore, is composed of 73,62 parts of pure nitric acid and 26,38 of water. But as Mr Kirwan has not proved that nitrat of foda contains no water, perhaps the proportion

bodies,

Its action on other

of water may be greater. He has rendered it probable, however, that nitrat of foda contains very little water.

Nitric acid is decomposed by a great variety of substances. When poured upon oils, it sets them on fire. This is occasioned by a decomposition both of the acid and oil. The oxygen of the acid combines with the carbon and with the hydrogen of the oils, and at the fame time lets go a quantity of caloric. Hence we fee that the oxygen which enters into the composition of the nitric acid, still contains a great deal of caloric; a fact which is confirmed by a great number of other phenomena. The combustion of oils by this acid was first taken notice of by Borrichius and Slare; but it is probable that Homberg communicated it to Slare. In order to fet fire to the fixed oils, it must be mixed with forne fulphuric acid; the reason of which seems to be, that these oils contain water, which must be previously removed. The fulphuric acid combines with this wa ter, and allows the nitric acid, or rather the oil and ni-tric acid together, to act. The drying oils do not require any fulphuric acid: they have been boiled, and confequently deprived of all moisture. It sets fire also to charcoal, provided it be perfectly dry. This fact was first observed by Proust, and afterwards confirmed by the Dijon academicians. It sets fire also to zinc, bismuth, and tin, if it be poured on them in fution, and to filings of iron, if they be perfectly dry t. In all these cases, the acid is decomposed. Sulphurated hydrogen gas also takes fire, and burns with a strong flame by means of this acid +. +Tromfdorff.

It is capable of oxydating all the metals except gold, platinum (x), and titanium. It appears, from the experiments of Scheffer, Bergman, Sage, and Tillet, that nitric acid is capable of diffolving (and confequently of oxydating) a very minute quantity even of gold.

Nitric acid combines with alkalies, alkaline earths, alumina, and jargonia, and with the oxyds of metals, and forms compounds which are called nitrats. It does not act upon filica nor adamanta.

And affini-The order of its affinities is as follows:

SECT. IV. Of Nitrous Acid.

Part

Na

Is oxygen gas he mixed with nitrous gas, a quantity of red fumes appear, which are readily abforbed by Com water. These red fumes are nitrous acid.

If a glass vessel containing nitric acid be inverted in time to another veffel containing the fame acid, and exposed cid. to the light, the inverted glass will become partly full of oxygen gas, and at the same time part of the nitric acid is converted into nitrous acid *. It follows, from * Man this experiment, that nitrous acid contains less oxygen Craff than nitric acid. Lavoisier has calculated, that it con- and the tains somewhat less than three parts of oxygen to one

Nitrous acid is of a brown or red colour, exceeding topped ly volatile, and emitting a very suffocating and scarcely ties. tolerable odour. When to this acid concentrated, a fourth part by weight of water is added, the colour is changed from red to a fine green; and when equal parts of water are added, it becomes blue †. Dr Priestley observed, that water impregnated with this acid in the flate of vapour became first blue, then green, and laftly yellow. A green nitrous acid became orangecoloured while hot, and retained a yellow tinge when cold. A blue acid became yellow on being heated in a tube hermetically sealed. An orange-coloured acid, by long keeping, became green, and afterwards of a deep blue; and when expoted to air, refumed its original colour. These colours seem to depend upon the concentration of the acid.

Dr Priestley found that water absorbed great quantities of this acid in the state of vapour; and that when saturated, its bulk was increased one-third.

In the state of vapour, it is absorbed rapidly by oils. Whale oil, by absorbing it, became green, thick, and heavier. It gradually decomposed the acid, retained the oxygen, and emitted the azot in the state of

It is absorbed by fulphuric acid, but seemingly with ill, III out producing any change; for when water is poured into the mixture, the heat produced expels it in the nfual form of red fumes f. The only fingular circum & The stance attending this impregnation is, that it disposes 144 the sulphuric acid to crystallize *. This fact, first ob. * III ferved by Dr Priestley in 1777 (Y), was afterwards p. 156 confirmed by Mr Cornette.

Nitrous acid appears capable of combining with most of the bodies with which nitric acid unites. The falts which it forms are called nitrites.

Its affinities have never been accurately examined. Bergman supposes them the same with those of nitric

Of

(x) Nitre, however, acts upon platinum, as Mr Tennant has proved. Phil. Tranf. 1797. Morveau had made the same observation in the Elemens de Chimie de l'Academie de Dijon.

(x) Bernhardt, however, relates, in 1765, that once, when he was distilling a mixture of ten pounds of nitre with an equal quantity of calcined vitriol, which he had put into a retort, to which was fitted an adapter between the retort and the receiver, which contained a quantity of water-he observed a considerable quantity of a white crystalline salt formed in the adapter, while the liquid acid passed as usual into the receiver. This salt was very volatile, fmoked strongly when it was exposed to the air, and exhaled a red vapour; it burnt, to a black coal, wood, feathers, or linen, as fulphuric acid does; and where a piece of it fell, it evaporated in form of a blood-red vapour, till the whole of it disappeared. Half an ounce of these crystals dissolved in water with spurting and histing, like that of a red hot iron dipped in water, and formed a green nitrous acid. Some of this falt being put into a bottle, which was not well stopped, entirely vanished. These crystals were evidently the same with Dr Priestley's. See Keir's Dictionary.

* Dr Hopes

& Vauquelin, Chim. xxii. 208.

Nitrous gas was first obtained by Dr Hales, but its properties were discovered by Dr Priestley. It may be procured by dissolving metals in nitric or nitrous acid, and catching the product by means of a pneumatic apparatus.

As nitrous acid is formed by combining nitrous gas and oxygen, it is evident that nitrons gas contains less oxygen than nitrous acid. According to Lavoisier, it is composed of two parts of oxygen and one of azot.

Nitrous gas is elastic, and invisible like common air.

It extinguishes light, and instantly kills all those animals that are obliged to breathe it. Its specific gravity, actor cording to Mr Kirwan, is 0,001458 ‡.

Dr Priestley found that water was capable of absorbing about one tenth of nitrous gas, and that by the absorption it acquired an astringent taste \emptyset . Water parts with all the nitrous gas it has imbibed on being frozen \dagger .

Neither phosphorus nor sulphur seem capable of de-

composing nitrous gas.

Mr Linck, professor at Rostoc, found, that three parts of nitrous gas and two of hydrogen gas, obtained by sulphuric acid and iron, are scarcely, or not at all, diminished when exposed to day-light over water. Common air is not more diminished by this admixture kept a long time: but the mixture itself of these two gases is diminished by the addition of new portions of nitrous gas. Mr Linck concludes, from this observation, that part of the oxygen of the nitrous gas combined with the hydrogen and formed water, and that the remaining oxygen and azet formed a mixture similar to the air of the atmosphere. Mr Vauquelin had previously made the same observation. The affinity of hydrogen, therefore, for oxygen is greater than that of azot *.

Oils imbibe nitrous gas with avidity, and decom-

pose it.

Nitric acid abforbs a vast quantity of it, and is by that means converted into nitrous acid.—Sulphuric acid

The most important property of nitrous gas is that of combining instantly with oxygen gas, and forming nitrous acid, which is instantly absorbed by water. This property induced Dr Priestley to use nitrous gas as a test of the purity of common air. He mixed together equal bulks of these substances, and judged of the purity of the air by the diminution of bulk. The apparatus used for this purpose, which consists of a graduative ted tube, has been called a cudiometer. This eudiometer has been greatly improved by Fontana, but it is still liable to uncertainty in its application. Perhaps the best eudiometer is sulphuret of potas, which, as Morveau has discovered, absorbs, on the application of heat, the whole oxygen in a given bulk of air almost instantaneously.

Dr Priestley found, that nitrous gas was decomposed

by passing electric explosions through it.

Let us now consider in what manner oxygen and azot are combined in the three substances which have

been juit described.

It can hardly be conceived that azot is capable of azot combining with three different proportions of oxygen, or typen and of being faturated with each: it is furely much more probable, that in nitrous gas the oxygen and azot faturate each other directly and completely; that nitrous acid is composed of nitrous gas and oxygen, and Suppl. Vol. I. Part I.

nitric acid of nitrous acid and oxygen. And this sup- Muriatic position is confirmed by confidering that the strength, of affinity by which the oxygen is retained in each of these substances is very different. Some substances, as light, are capable of decomposing nitric acid, by seizing fome of its oxygen, and of converting it into nitrous acid; but they have no effect whatever upon nitrous acid or nitrous gas. Others, as bismuth, copper, phofphorus, and fulphur, are capable of decomposing both nitric and nitrous acids, but are incapable of altering nitrous gas: And others, again, as carbon, zinc, and iron, are capable of decomposing all the three. Every body which is capable of decomposing nitrous acid is capable also of decomposing uitric acid; and every body that decomposes nitrous gas is capable also of decomposing the other two. But the reverse of this is not true. The affinity of oxygen, then, for azot, nitrous gas, and nitrous acid, is different : oxygen lias a stronger affinity for azot than it has for nitrous gas, and a ftronger affinity for nitrous gas than for nitrous acid. But if all these bodies were direct combinations of azot and oxygen, how could this difference of affinity take place? Is it reasonable to suppose, that a substance has a stronger affinity for one proportion of any other body than for another proportion? or that, if such a difference existed, the strongest affinity should not always prevail? Mix together nitric acid and nitrous gas in proper proportions, and the whole mixture is converted into nitrous acid: but mix nitrous and nitric acids together, and no change whatever is produced. In the first case, is it not evident that the affinity of nitrous gas for oxygen is greater than that of nitrous acid; that therefore it decomposes the nitric acid, deprives it of oxygen, and leaves it in the state of nitrons acid? But, in the fecond case, no change can take place, because nitrie acid is composed of nitrous acid and oxygen; and it would be abfurd to suppose, that nitrous acid has a stronger affinity for oxygen than nitrous acid has. But were azot and oxygen capable of uniting in various proportions, why should not a mixture of nitric and nitrous acids, or of nitrous gas and nitrous acid, form new fubstances? And why are the only substances which appear in decompositions nitrous acid and nitrous gas? Surely these reasons are sufficient to shew us, that these bodies are combined in the following manner:

Azot and
Oxygen
Nitrous gas
and oxygen
Nitrous acid
and oxygen

form nitrous acid;
form nitric acid.

Perhaps there may be even more links in the chain than we are aware of. The dephlogifticated uitrous air of Dr Priestley, which Dieman and Van Troostwyck have lately proved to be composed of 37 parts of oxygen and 63 of azot, and of which little more is known than that it supports stame, is noxious to animals, abforbed by water, and only obtained by means of substances capable of decomposing nitrous gas—perhaps this air is composed directly of oxygen and azot, nitrous gas of this air and oxygen, and so on. There may be even links still farther back than that.

SECT. V. Of Muriatic Acid.

MURIATIC acid appears to have been known to Basil of muriatis
Valentine; but Glauber was the first who extracted it acid.

Rr from

I From mumarine acid, and now, pretty generally, muriatic acid ‡.

It is tometimes prepared by mixing one part of common falt with feven or eight parts of clay, and distilling the mixture. The clay, in this instance, is supposed to act chiefly by means of the fulphuric acid which it always contains (z): But this subject still requires farther elucidation. By these processes, muriatic acid is obtained diffolved in water. Dr Priestley discovered, that by applying heat to this folution, and receiving the product in veffels filled with mercury, a gas was procured; which gas is muriatic acid in a state of purity.

Muriatic acid gas is invisible and elastic, like common air. It destroys life and extinguishes slame. A candle, just before it goes out in it, burns with a beautiful green, or rather light blue flame; and the same * Priestley, slame appears when it is first lighted again *.

ties.

The specific gravity of muriatic acid in the state of and oils by its affinity for water *. gas is, according to Mr Kirwan +, 0,002315, which is nearly double that of common air.

Water absorbs this gas with avidity. Ten grains of water are capable of absorbing ten grains of the gas. The folution thus obtained occupies the space of 13,3 grains of water nearly. Hence its specific gravity is 1,50, and the denfity of the pure muriatic acid in it is 3,03 * (A).

* Kirwan, Irish Trans. vol. iv.

various

denfities.

As muriatic acid can only be used conveniently when diffolved in water, it is of much confequence to know how much pure acid is contained in a given quantity of

liquid muriatic acid of any particular denfity.

Now the specific gravity of the purest muriatic acid it contained that can eafily be procured and preserved, is 1,196; it would be needlefs, therefore, to examine the purity of any muriatic acid of fuperior denfity. Mr Kirwan calculated that muriatic acid, of the denfity 1,196, contains 40 parts of acid of the denfity 1,500, which he took for the standard; then, by means of experiments, he formed the following table:

at the spe- cific gra- vity	contain of stan- dard acid	at the spe- cific gra- vity	contain of flan- dard acid	at the spe- cific gra- vity	contain of ftan- lard acid

Muriatic acid (for this solution of the acid in water

Muriatic from common falt by means of fulphuric acid. Com- is always called by that name) is generally of a pale Oxy-muria mon falt is composed of muriatic acid and soda, for yellow colour, owing, as Dr Priestley supposed, to some tic Adid which last substance sulphuric acid has a stronger affini- earthy matter diffolved in it; but much more probably ty. This acid was first called spirit of salt, afterwards to its having absorbed a quantity of oxygen, for which it has a strong affinity. Indeed, that this is the cause appears evidently from Dr Priestley's own observations; for it was destroyed only by those bodies which had a stronger affinity for oxygen. It is very volatile, as might be expected, constantly emitting white sumes of a peculiar and unpleasant odour.

Muriatic acid is capable, by the affiftance of heat, of its action oxydating the following metals: Iron, tin, lead, zinc, on other bismuth, cobalt, nickel, manganese, antimony. arfenic. bodies. Several of these, as iron, for instance, it oxydates even

without the affistance of heat.

At a boiling heat, it oxydates filver and copper. It has no action on gold, platinum, mercury, tungsten, molybdenum, tellurium, titanium. Its action on uranium has not been tried.

In the state of gas, it appears to decompose alcohol

It is capable of diffolving a little fulphat and fluat + 11. 281. + See fest. of lime, and arfeniat of mercury.

It combines with the alkalies, alkaline earths, alumina, and jargonia, and with most of the metallic oxyds, and forms neutral falts, known by the name of muriats.

Morveau first shewed, that this acid, in the state of Destroys gas, neutralized putrid miasmata, and by that means putrid miadestroyed their bad effects. In 1773, the cathedral of Dijon was so infected by putrid exhalations, that it was deserted, after feveral unsuccessful attempts to purify it. Application was made to Mr Morveau to fee whether he knew any method of destroying these exhalations. He poured two pounds of fulphuric acid on fix pounds of common falt, contained in a glass capfule, which had been placed on a few live coals in the middle of the church. He withdrew precipitately, and shut all the doors. The muriatic acid gas foon filled the whole cathedral, and could even be perceived at the door. After 12 hours, the doors were thrown open, and a current of air made to pass through to remove the gas. This destroyed completely every putrid odour +.

The affinities of muriatic acid are as follows:

† Jour. de Phys. 436 427 Its affinition Barytes. Potals, Strontites 1, Lime, Magnesia, Ammonia, Alumina, Jargonia *, * Vauguelit Metallic oxyds as in fulphuric acid, Ann. de Chim. xxiii Water.

SECT. VI. Of Oxy-muriatic Acid.

Pur into a glass retort one part of the black oxyd Discover of manganese and three parts of muriatic acid; place and prepare it in a fand-bath in such a manner that the liquor which ration of rifes up into the neck of the retort may fall back again oxy-murib

(z) Morveau has shown, that even alumina contains sulphuric acid, provided a precipitation, on adding muriat of barytes, be a fufficient test.

(A) For let D = the density of a mixture; m the weight of the denser ingredient; d its density; l the weight of . held day / and an

d. water in it, luted to the retort merely by a fillet of brown paper. In about a quarter of an hour the receiver will appear filled with a yellow coloured gas; it is then to be removed, and others applied successively till the operation be finished.

This gas is oxy-muriatic acid, first discovered by Scheele, while he was making experiments on manganefe, and called by him dephlogiflicated muriatic acid, because he thought it muriatic acid deprived of phlogiston. The French chemists called it oxygenated muriatic acid, which Dr Pearson contracted into oxy-muriatic acid; and this last name we have adopted, because it

is shorter and equally distinct.

The true theory of the formation and composition of this acid, which was first given by Berthollet, will appear from the following facts: The black oxyd of manganese is, during the process, converted into white oxyd, and must therefore have given out a quantity of oxygen. When oxy-muriatic acid diffolved in water is presented to the light in a vessel half empty, oxygen gas is difengaged and floats above, and the acid is converted into common muriatic acid: Confequently oxymuriatic acid is composed of muriatic acid and oxygen. Black oxyd of manganese is composed of white oxyd and oxygen; muriatic acid has a stronger affinity for oxygen than the white oxyd; during the distillation the black oxyd is decomposed, the oxygen combines with muriatic acid, and the product is oxy-muriatic

Oxy-muriatic acid gas is of a yellow colour. It fupports flame, but cannot be breathed without proving noxious. The death of the ingenious and industrious Pelletier, to whom we have so often referred, was occafioned by his attempting to respire it. A consumption was the consequence of this attempt, which, in a short

time, proved fatal.

s per-

It does not unite readily with water. Scheele found, that after standing 12 hours over water, 4ths of the gas were absorbed: the remainder was common air, which no doubt had been contained in the vessel before the operation. Berthollet furrounded feveral bottles containing it with ice: as foon as the water in these bottles was faturated, the gas became concrete, and funk to the bottom of the veffels; but the smallest heat made it rife in bubbles, and endcavour to escape in the form of * ur. de gas *. Westrum observed that it became solid when P: 1785 exposed in large vessels to the temperature of 40°; and ur. de that then it exhibited a kind of crystallization +. The specific gravity of water saturated with this gas at the

into the vessel; and apply a small receiver, with a little temperature of 43°, is 1,003 ‡. Water impregnated Oxy-muriwith it has not an acid, but an austere taste &, unlike atic Acid. that of other acids.

It renders vegetable colours avhite, and not red, as your. de other acids do; and the colour thus destroyed can Phys. 1785. neither be restored by acids nor alkalies. It has the Scheele. fame effects on yellow wax. If the quantity of vegetable colours to which it is applied be fufficiently great, it is found reduced to the flate of common muriatic acid. Hence it is evident, that it destroys these colours by communicating oxygen. This property has rendered oxy-muriatic acid a very important article in bleaching.

Nitrous gas, hydrogen, fulphur, fulphurous acid, and phosphorus, decompose this acid, by depriving it of its oxygen, and leaving the muriatic acid in a separate state. Phosphorus, however, does not produce this effect so

readily, except when affifted by heat *.

When muriatic acid is mixed with nitric acid, the Fneyel.

Method. compound has precifely the smell and the qualities of Chimie I. oxy-muriatic. It can scarcely be doubted, therefore, 251. that as far as it acts as an acid, different from the mu-riatic and the nitric, it is nothing else but oxy-muriatic riatic acid.

This mixture of the two acids was formerly called aqua regia; but at present it is called by the French chemists nitro-muriatic acid. It is first mentioned by Isaac the Hollander, and seems to have been known before the muriatic acid itself. It was prepared by pouring nitric acid on common falt. The nitric acid decomposes the falt, and part of it unites with the muriatic acid thus fet at liberty.

Oxy-muriatic acid oxydates all the metals (except, It, action perhaps, titanium) without the assistance of heat. It decomposes red sulphuret of mercury, or cinnabar, bodies.

which neither fulphuric nor nitric acid is able to ac-

complish +.

All the fubstances placed before muriatic acid in the Bergman, table of the affinities of oxygen, are capable of decompofing this acid. Many of them, when plunged into it while in the state of gas, actually take fire. Westrum observed, for inftance, that when pieces of wood were plunged into this gas, they took fire; that arenic burned with a blue and green flame; bifmuth, with a lively bluish flame; nickel, with a white flame, bordering on yellow; cobalt, with a white flame, approaching to blue; zinc, with a lively white flame; tin, with a feeble bluish flame; lead, with a sparkling white flame; copper and iron, with a red flame: that powdered charcoal took fire in it at the temperature of 90°, and that ammonia produced with it a loud detonation ‡.

With & Four. de xxxvii. 385.

an equal bulk of water; and m', d', and l', the fame elements of the rarer: Then $D = \frac{m+m'}{l+l'}$. In the above case, m + m' = 20, and l + l' = 13.3. Then $D = \frac{20}{13.3} = 1.5$. Now to find the specific gravity of the condensed muriatic acid gas, we have from the above equation $l = \frac{m + m' - l'D}{D} = \frac{5}{1.5} = 3.3$; and $d = \frac{1}{1.5} = \frac{1}{1.$

 $\frac{m}{l} = \frac{10}{3.3} = 3.03$. See Irish Transactions, vol. iv.

This calculation, however, is formed upon the supposition that the water suffers no condensation at all—a supposition certainly contradicted by every analogy, and which, as Mr Keir has shewn, the experiments mentioned in Mr Kirwan's first paper are insufficient to prove.

Oxy-muriatic Acid. pable of combining and forming neutral falts, which have been called oxy-muriats.

1 lte affinities The affinities of this acid, according to Lavoisier, are as follows:

* Vauquelin, Ann. de Chim XXII. 208.

Alumina, Jargonia *? Ammonia, Oxyd of antimony, - Silver, Arfenic. Barytes, Strontites? Oxyd of bismuth, Lime, Oxyd of cobalt, - Copper, Tin, Iron, Magnefia (B), Oxyd of manganefe, - Mercury, Molybdenum, Nickel, - Gold, - Platinum, Lead, Potafs, Soda, Oxyd of tungsten, - Zinc (c).

Of the component parts of muriatic acid.

The component parts of muriatic acid are still imperfectly known. Dr Girtanner pretended, about the year 1790, that he had decomposed it; and that it confisted of hydrogen combined with a greater proportion of oxygen than enters into the composition of water. He passed electrical explosions through muriatic acid, and obtained a quantity of oxygen and hydrogen gas. But a repetition of these experiments shewed, that the gases were owing, not to the decomposition of the acid, but to that of the water with which the acid was combined.

The experiments of Mr Lambe (D) have lately opened a new and unexpected path, which feems to lead directly to the discovery of the component parts of this acid. He found, that when iron was acted upon by sulphurated hydrogen gas, a substance was produced which possessed all the properties of oxy muriat of iron (oxymuriatic acid combined with iron). The sulphurated hydrogen gas which he used was obtained from sulphuret of iron, formed by susing equal parts of iron and flowers of sulphur; and it was extricated by diluted sulphuric acid. In a solution of this gas in distilled water, he digested iron-silings, previously purified by repeated washings with distilled water. The bottle was filled with the solution, and corked. The iron was presently acted upon; numerous bubbles arose, which drove the cork

out of the bottle; they were strongly inflammable, and Phosphon probably, therefore, pure hydrogen gas. The liquor gradually loft its odour of sulphurated hydrogen gas, and after some days smelled very much like stagnant rain-water. As the bubbles ceased to be produced, it recovered its transparency. On evaporating a small quantity of this folution in a watch-glass to drynes, a bitter deliquescent salt was left behind. On this salt a little fulphuric acid was dropped, and paper moistened with ammonia was held over the glass; white vapours were immediately formed over the glass; and consequently some volatile acid was separated by the fulphuric acid. Mr Lambe evaporated about eight ounce-measures of the same liquor, and, as before, dropped a little fulphuric acid on the residuum; a strong effervescence was excited, very pungent acid fumes arole, which, from their fmell, were readily known to be muriatic. The fame truth was established beyond a doubt. by holding a bit of paper moistened with water, which made the vapours visible in the form of a grey smoke; a distinguishing characteristic, as Bergman has observed, of the muriatic acid. - When manganete and mercury were diffolved in fulphurated hydrogen gas, the falts formed gave the same unequivocal marks of the prefence of muriatic acid +.

Shall we conclude from these facts, that the basis of ibid, muriatic acid is sulphurated hydrogen; that muriatic acid is sulphurated hydrogen combined with oxygen; that this combination takes place during the solution of the iron; and that the escape of hydrogen is owing to the decomposition of the water?

SECT. VII. Phosphoric Acid.

Phosphorus is capable of forming combinations Different with two different quantities of oxygen; with the of phospholarger it forms phosphoric; and with the smaller phosphorus acid.

Phosphoric acid was unknown till after the discovery of phosphorus. Boyle is perhaps the first person who mentions it: he discovered it by allowing phosphorus to burn slowly in common air. But Margrat was the first person who examined its properties, and discovered it to be a peculiar acid.

It may be procured by exposing phosphorus to a moderate heat: the phosphorus takes fire, combines with oxygen, and is converted into an acid.

It may also be prepared by exposing phosphorus 436 during f me weeks to the ordinary temperature of the preparing atmosphere, even in winter; when the phosphorus undergoes a flow combustion, and is gradually changed into a liquid acid. For this purpose, it is usual to put small pieces of phosphorus on the inclined side of a glass sunnel, through which the liquor which is formed drops into the bottle placed to receive it. From one ounce of phosphorus about three ounces of acid liquor may be thus prepared, called phosphoric acid by deliquescence.

Scheele has contrived another mode of obtaining the phosphoric

⁽B) According to Tromsdorf, oxy-muriatic acid is incapable of combining with magnesia. Ann. de Chim.

⁽c) This is the order of the affinities of nitro-muriatic acid. Many facts (some of which shall appear afterwards) concur to prove that the affinities of the oxy-muriatic acid are the same, and indeed that they are the same acids.

⁽D) Analysis of the waters of two mineral springs at Leminton Priors. Manchester Memoirs, vol. V. part 1st.

phosphoric acid from phosphorus without combustion, by the mere action of the nitric acid on phosphorus ‡. Mr Lavoisier has repeated and described this process &. He put two pounds of nitric acid, the specific gravity of which was 1,29895, into a retort, the contents of which were equal to fix or feven French pints, and to which a balloon was fitted. Having placed this retort in a fand-bath, and brought the heat of the acid contained in it to 1334 deg. he added fuccessively small quantities of phosphorus, about ten or twelve grains at a time, until he had diffolved 23th oz. At first the effervescence was great, but at last he was obliged to apply heat to effect the folution. The operation lasted 17 or 18 hours. A good deal of nitrons acid had passed into the receiver. He then poured the contents of the retort into a smaller retort, and evaporated by means of a stronger heat, until the phosphoric acid began to distil in white vapours. The remaining acid was so thick, that he could not pour it out of the retort, and therefore could not ascertain its quantity; but he supposes it might be eight or nine ounces, in which he thinks there were about 21 ounces of phosphorus; the remaining 1 ounce being supposed to have evaporated. The quantity of oxygen imbibed he reckons at 31 ounces, and the quantity of water at about 2 ounces.

Lavoisier computes, that phosphoric acid contains 100 parts of phosphorus and 154 of oxygen.

The colour of this acid is white; it has no smell,

has an acid taste; but is not corrosive (E).

It is exceedingly fixed. When exposed to the fire in a matrass with a long neck, it loses at first the greater part of its water; then an odour of garlic is felt, owing to some phosphorus, from which it is exceedingly difficult to clear it entirely; there is likewise a small quantity of the acid volatilized along with the water. The liquor then becomes thick and milky: fmall luminous decrepitations take place from time to time, and they continue for some time after the veffel is taken from the fire. If the matter be then put into a crucible, and placed among burning coals, it first boils violently, and gives out a vapour which tinges flame green, and is at last converted to a white transparent glass, infoluble in water.

The specific gravity of this acid in a state of dryness is 2,687 +, that of phosphoric acid by deliques-" w. cence 1,417 *. It is capable of crystallizing; its crystals are quadrangular prisms terminated by quadrangu-

lar pyramids. Phosphoric acid obtained by deliquescence, when mixed with an equal quantity of diffilled water, acquired so little heat as to raise the thermometer only one

degree, as Mr Sage observed.

Mr Lavoisier raised Reaumur's thermometer from 8° to 14° or 15° by mixing phosphoric acid boiled to the confistence of a syrup, with an equal quantity of water; and from 8° to 32° or 33° when the acid was as thick as turpentine *.

Phosphoric acid is capable of oxydating iron, tin, lead, zinc, antimony, bismuth, manganese. When fufed with feveral of these metals, as tin, lead, iron, and zinc, it is converted into phosphorus; a proof that they

have a stronger affinity for oxygen.

It does not act upon gold, platinum, filver, copper, Boracic mercury, arfenic, cobalt, nickel It appears, however, to have fome action on gold in the dry way, as it is called; for when fused with gold-lear it assumes a purple colour; a proof that the gold has been oxydated.

It is capable of combining with alkalies, alkaline earths, alumina, and metallic oxyds; and of forming

falts, known by the name of phosphats.

Phosphoric acid, by the affishance of heat, is capable of decomposing glass.

Its affinities are as follows:

oxygen than phosphoric acid.

Barytes, Strontites ± Magnefia, Potals,

Ammonia, Alumina.

temperature of the atmosphere; but it gradually absorbs rous acids. more oxygen, and is converted into phosphoric acid. Concerning phosphorous acid nothing of any confequence is at present known, except that it contains less

SECT. VIII. Boracic Acid.

THE word borax first occurs in the works of Geber, an Arabian chemist of the tenth century. It is a name given to a species of white falt much used by various artists. Its use in soldering metals appears to have been known to Agricola.

Borax is found mixed with other substances in Thibet. It seems to exist in some lands adjacent to lakes, from which it is extracted by water, and deposited in those lakes; whence in summer, when the water is shallow, it is extracted and carried off in large lumps. Sometimes the water in these lakes is admitted into refervoirs, at the bottom of which, when the water is exhaled by the fummer's heat, this falt is found. Hence it is carried to the East Indies, where it is in some measure purified and crystallized: in this state it. comes to Europe, and is called tincal. In other parts of Thibet, it feems, by accounts received from China, they dig it out of the ground at the depth of about two yards, where they find it in small crystalline masses, called by the Chinese mi poun, hour poun, and pin poun; and the earth or ore is called pounxa *.

Though borax has been in common use for nearly in 37 three centuries, it was only in 1702 that Homberg, by distilling a mixture of borax and green vitriol, discovered Discovery the boracic acid. He called it narcotic or fedative falt, of boracic from a notion of his, that it possessed the properties in-acid. dicated by these names. In his opinion, it was merely a product of the vitriol which he had used; but Lemery the Younger foon after discovered, that it could likewife be obtained from borax by means of the nitric and muriatic acids. Geoffroi afterwards discovered,

(E) We have observed, however, that when very much concentrated it destroyed the texture of vegetable substances, paper, for instance, very completely.

Its affinities

Tran/

Borage

Acid

that borax contained foda; and at last Baron proved, by a number of experiments, that borax was composed of boracic acid and foda; that it might be reproduced by combining thefe two substances-and that therefore the boracic acid was not formed during the decompofition of borax, as former chemists had imagined, but was a peculiar substance which pre-existed in that salt.

443 Attempts

And to

This conclusion has been called in question by Mr to prove that it doe. Cadet *; who affirmed, that it was composed of foda, not exist in the vitrifiable earth of copper, another unknown metal, and muriatic acid. But this affertion has never been con-* Fourn. de firmed by a fingle proof; Mr Cadet has only pro-Phy. 1782 ved, that boracic acid fometimes contains copper; and Beaumé's experiments are sufficient to convince us, that this metal is merely accidentally prefent, and that it is probably derived from the veffels employed in crystallyzing borax: That boracic acid generally contains a with which it is combined in borax: And that crude borax contains a quantity of earth imperfectly faturated with boracic acid: -All which may be very true; but they are altogether infufficient to prove that boracic acid is not a peculiar substance, fince it displays properties different from every other body.

Messrs Exschaquet and Struve have endeavoured, on prove that the other hand, to prove, that the phosphoric and boit is phose racic acids are the same. But their experiments merephoric acid ly shew, that these acids resemble one another in several particulars; and though they add confiderably to our knowledge of the properties of the phosphoric acid, they are quite inadequate to establish the principle which these chemists had in view; since it is not sufficient to prove the identity of the two acids, to shew us a refemblance in a few particulars, while they differ in many others. Boracic acid must therefore be considered as a distinct substance, the component parts of which

are entirely unknown.

The easiest method of procuring boracic acid is the procuring following one: Diffolve borax in hot water, and filter the folution; then add fulphuric acid, by little and little, till the liquor be rather more than faturated. Lay it afide to cool, and a great number of small, shining, laminated crystals will form. These are the boracic acid. They are to be washed with cold water, and drained

upon brown paper. 446

Its proper-

* Reuss

dat. 1778.

This acid has a fourish taste at first, then makes a bitterish cooling impression, and at last leaves an agreeable sweetness. Its crystals have some resemblance to spermaceti, and it has the same kind of feel.

It changes vegetable blues to red; it has no fmell; but when fulphuric acid is poured on it, a transient odour of musik is produced *. The air produces no De Sale Se- change on it.

According to Reufs, it is foluble in 20 parts of cold water, eight parts of warm water, and 2,5 of boiling water. According to Wenzel, 960 grains of boiling water diffolve 434 of this acid. According to Morveau, one poundof boiling water diffolves only 183 grains.

It is exceedingly fixed when not combined with water. When exposed to a violent fire it is converted into a white transparent glass; which, however, is soluble in water, and produces the acid again by evaporation.

Boracic acid is also foluble in alcohol; and alcohol * Kirwan's containing it burns with a green flame.

Miner. ii. 4. Its specific gravity is 1,479 t.

Paper dipped into a folution of boracic acid burns with a green flame.

Though mixed with fine powder of charcoal, it is nevertheless capable of vitrification; and with foot it melts into a black bitumen-like mass, which is, however, foluble in water, and cannot be easily calcined to ashes, but sublimes in part +.

With the affiftance of a distilling heat it dissolves in Didical oils, especially in mineral oils; and with these it yields fluid and folid products, which give a green colour to

spirit of wine.

When boracic acid is rubbed with phosphorus, it does not prevent its inflammation; but an earthy yellow matter is left behind +.

It is hardly capable of oxydating, or diffolving any of the metals except iron and zinc, and perhaps copper. Its action

Boracic acid combines with alkalies, alkaline earths, bodies little of the acid employed to separate it from the soda, and alumina, and most of the metallic oxyds, and forms compounds, which are called borats.

Its affinities are as follows:

Lime, Barytes, Strontites 1, Magnesia, Potafs, Soda, Ammonia, Oxyd of zinc, iron, - lead, ____ tin, --- cobalt, - copper, - nickel, -- mercury, Alumina, Jargonia f, Water, Alcohol,

SECT. IX. Fluoric Acid.

THE mineral called fluor or fufible spar, was not pro-Different perly distinguished from other spars till Margraf pu-of show blished a differtation on it in the Berlin Transactions for acid. 1768. He first proved, that it contained no sulphuric acid, as had been formerly supposed; he then attempted to decompose it, by mixing together equal quantities of this mineral and fulphuric acid, and diftilling them. By this method he obtained a white fublimate, which he supposed to be the fluor itself volatilized by the acid. He observed, with astonishment, that the glass retort was corroded, and even pierced with holes. Nothing more was known concerning fluor till Scheele published his experiments three years after; by which he proved, that it was composed chiefly of lime and a particular acid, which has been called fluoric acid.

To obtain it, put eight ounces of finely powdered Method fluor into a retort, and pour on it an equal quantity of ohtain fulphuric acid, and lute to the retort, as exactly as pof-it. fible, a receiver containing eight ounces of water. Vapours immediately appear and darken the infide of the veffel: These are the acid in the state of gas. The diftillation is to be conducted with a very moderate heat, not only to allow the gas to condense, but also to prevent the fluor itself from subliming. After the pro-

cefs, a crust of white earth is found in the receiver,

which has all the properties of filica.

Scheele supposed, that the filica produced was formed of fluoric acid and water; and Bergman adopted the fame opinion. But Wiegleb and Buccholz shewed, that the quantity of filica was exactly equal to what the retort lost in weight; and Meyer completed the proof that it was derived from the glass, by the follow. ing experiment: He put into each of three equal cylindrical tin vessels a mixture of three oz. of sulphuric acid and one oz. of fluor, which had been pulverized in a mortar of metal. Into the first he put one oz. of pounded glass; into the second, the same quantity of quartz in powder; and into the third, nothing. Above each of the vessels he hung a sponge moistened with water; and having covered them, he exposed them to a moderate heat. The sponge in the first cylinder was covered with the crust in half an hour; the sponge in the second in two hours; but no crust was formed in the third, though it was exposed several days. In consequence of this decisive experiment, Bergman gave up his opinion, and wrote an account of Meyer's experiment to Morveau, who was employed in translating his works, to enable him to correct the mistake in his notes.

Soon after the discovery of this acid, difficulties and doubts concerning its existence as a peculiar acid were flarted by some French chemists, dilguised under the name of Boulanger, and afterwards by Mr Achard and Mr Monnet. To remove these objections, Mr Scheele instituted and published a new set of experiments; which not only completely established the peculiar nature of the fluoric acid, but once more displayed the unrivalled abilities of the illustrious discoverer. These important particulars we pass over thus slightly, because they have been partly treated of already in the article CHEMISTRY (Encycl.). One experiment, however, we cannot omit, because it is sufficient of itself to destroy almost all the objections of his antagonists, which consisted in attempting to prove, that the fluoric acid was merely a modification of the acid employed to extract it. We

shall give it in Mr Scheele's own words.

"I melted together (fays he) in a crucible two ounces of finely pulverized fluor spar with four ounces of potals. As foon as they were melted, I poured out the mass, rubbed it, when it was become cold, to a powder, and extracted the alkali from it again by lixiviation with water. I evaporated the lixivium to dryness; and threw away the remaining undiffolved powder (which was only one of the component parts of the fluor, and which diffolved readily, and with effervescence, in acids) from its folution in which it may be precipitated by fulphuric acid in the form of felenite (fulphat of lime). Upon a little of the dried alkali, put into a small retort, I poured some sulphuric acid, sitted to it a receiver containing some water; and even before the retort was become hot, I observed this water to be covered over with a pellicle of filiceous earth: a certain proof that the alkali had extracted the acid from the fluor during its exposure to the fire with it. Should Mr Achard, agreeably to the opinion which he has adopt-

ed, conclude from this experiment, that the alkali fe- Fluoric parated the volatile earth from the fluor (F); still he must certainly allow this earth of his to be of an acid nature, fince the alkali is capable of difengaging it from the calcareous earth.-The remaining portion of the dried alkali I diffolved again in water, and faturated the superfluous alkali with pure nitric acid. After expelling from this faturated folution, by means of heat, the carbonic acid gas, which in fuch cases is always retained in the liquor, I dropped some of it into lime-water ;. whereupon I obtained a white precipitate, which was a regenerated fluor. I now diffolved fome oxyd of lead in vinegar, and continued to add to the ley, which had been faturated with nitric acid, as much of this folution as was requifite, till all precipitation ceased. Thus I transferred the fluor acid from the alkali to the oxyd. After washing the precipitate in cold water, and drying it, I dropped upon a small quantity of it a few drops of fulphuric acid: a frothing up immediately enfued, accompanied with an extrication of fluor acid. vapours. But perhaps, in this case, the volatile earth of fluor unites with the fulphuric acid, and convertsthis fixed, or almost fixed acid into acid gas. I can eafily make allowance to Dr Priestley for being inclined to draw fuch a conclusion, fince this celebrated philosopher does not pretend to be a chemist (G). Being defirous of feeing whether heat alone was capable of expelling this acid from the oxyd of lead, I put a little of this fluorated oxyd into a small retort, the receiver to which contained some water. The oxyd was melted; but I could not perceive any acid. The bottom of the retort was moreover quite corroded and diffolved, fo that the whole ran into the fire. Thus the oxyd of lead retains this acid in the fire, and will not part with it, unless the oxyd is combined with some other substance. I therefore rubbed the remainder of my fluorated oxyd of lead with an equal quantity of charcoal powder, and diffilled the mixture in an open fire in a fmall glass retort, to which was adapted a receiver containing some water. As soon as the reduction of the oxyd of lead took place, the neck of the retort became incrusted with a white sublimate, and a siliceous pellicle appeared upon the water. The fublimate had a four taile, because the filiceous earth of which it consists is penetrated with fluoric acid; and the acid water in the receiver let fall, on the addition of volatile alkali, a filiceous earth +."

Silica, Alcohol.

SECT. X. Of Carbonic Acid.

CARBONIC acid is composed of carbon and oxygen According to Lavoisier's experiments, the proportions are 28 parts of carbon and 72 of oxygen. Mr Prouse informs us, that there is also a carbonous acid (H); but with this acid we are not at present acquainted, and cannot therefore describe it.

257 Cannot therefore describe it.

Diffeovery Paracellus and Van Helmont were acquainted with of carbonic the fact, that air is extricated from folid bodies duacid.

produced the name of gas. Boyle called these kinds of air artificial airs, and suspected that they might be different from the air of the atmosphere. Hales ascertained the quantity of air that could be extricated from a great variety of bodies, and shewed that it formed an effential part of their composition. Dr Black proved, that the fubftances then called lime, magnefia, and alkalies, are compounds, consisting of a peculiar species of air, and pure lime, magnefia, and alkali. To this species of air he gave the name of fixed air, because it existed in these bodies in a fixed state. This air or gas was afterwards investigated by Dr Priestley, and a great number of its properties ascertained. From these properties Mr Keir + first concluded that it was an acid; + Kir'. and this opinion was foon confirmed by the experiments Macque of Bergman, Fontana, &c. Dr Prieftley at first sufpected that this acid entered as an element into the composition of atmospherical air; and Bergman adopting the same opinion, gave it the name of aerial acid. Mr Bewdly called it mephitic acid, because it could not be respired without occasioning death; and this name was also adopted by Morveau. Mr Keir called it calcareous acid; and at last Mr Lavoisier, after discovering its composition, gave it the name of carbonic acid gas.

The opinions of chemists concerning the composition Theor of carbonic acid have undergone as many revolutions as about its name. Dr Prieftley and Bergman feem at first to compos have confidered it as an element; and several celebrated chemists maintained that it was the acidifying principle. Afterwards it was discovered that it was a compound, and that oxygen gas was one of its component parts. Upon this discovery the prevalent opinion of chemists was, that it confifted of oxygen and phlogiston; and when hydrogen and phlogiston came (according to Mr Kirwan's theory) to fignify the fame thing, it was of courfe maintained that carbonic acid was composed of oxygen and hydrogen: and though Mr Lavoisier demonstrated, that it was formed by the combination of carbon and oxygen, this did not prevent the old theory from being maintained; because carbon was itself confidered as a compound, into which a very great quantity of hydrogen entered. But after Mr Lavoisier had demonstrated, that the weight of the carbonic acid produced was precifely equal to the carbon and oxygen employed; after Mr Cavendish had discovered that oxygen and hydrogen when combined did not form carbonic acid, but water-it was no longer possible to hesitate that this acid was composed of carbon and oxygen. Accordingly all farther dispute about it seems now at an end. At any rate, as we have already examined the objections that have been made to this conclusion, it would be improper to enter upon them here.

If any thing was still wanting to put this conclusion beyond the reach of doubt, it was to decompound carbonic acid, and thus to exhibit its component parts by analysis as well as synthesis. This has been actually done by the ingenious Mr Tennant. Into a tube of glass he introduced a bit of phosphorus and

(H) When there are two acids having the same base, but containing different quantities of oxygen, they are distinguished by their termination. The name of that which contains most oxygen ends in ic, the other in ous. Thus sulphuric and sulphurous acids, nitric and nitrous, phosphoric and phosphorous, carbonic and carbonous.

onic some carbonat of lime. He then sealed the tube hermetically, and applied heat. Phosphat of lime was formed, and a quantity of carbon deposited. Now phosphat of lime is composed of phosphoric acid and lime; and pholphoric acid is compoled of pholphorus and oxygen. 'The fubflances introduced into the tube were phosphorus, lime, and carbonic acid; and the substances found in it were phosphorus, lime, oxygen, and carbon. The carbonic acid, therefore, must have been decomposed, and it must have consisted of oxygen and carbon. This experiment was repeated by Dr Pearson, who afcertained that the weight of the oxygen and carbon were together equal to that of the carbonic acid which had been introduced; and in order to shew that it was the carbonic acid which had been decomposed, he introduced pure lime and phosphorus; and instead of obtaining phosphat of lime and carbon, he got nothing but phosphuret of lime. These experiments were also confirmed by Messirs Fourcroy, Vauquelin, Sylvestre, and Broigniart (1) +.

Carbonic acid may be obtained by pouring fulphuric acid upon chalk, and receiving the product in a pneu-

matic apparatus.

It is invisible and elastic like common air. It extinguishes a candle, and is unfit for respiration. It has no

Its specific gravity is 0,0018‡; but this varies according to its dryness or moisture.

SECT. XI. Of Acetous Acid.

Acetous acid or vinegar was known many ages before the discovery of any other acid, those only excepted which exist ready formed in vegetables. It is mentioned by Moses, and indeed seems to have been in common use among the Israelites and other eastern nations at a very early period.

The methods of procuring, purifying, and concentrating this acid, have been already given in the articles Chemistry, Fermentation, and Vinegar (Encycl.) and cannot therefore be repeated in this place.

It has been ascertained beyond a doubt, that this acid is composed of carbon, hydrogen, and oxygen; but neither the manner in which these substances are combined, nor their proportions, have been accurately

Acetous acid, as commonly prepared, is very fluid, Lowitz's has a pleafant fmell, and an acid tafte. It reddens ve-obtaining getable colours. In this flate it is mixed with a great pure aceproportion of water; but Mr Lowitz of Petersburg has tous acid. discovered, that it may be obtained in a solid crystallized form. Of this curious and instructive process we fhall transcribe his own account *. * Crell's

" I have long been accustomed (fays he) to prepare Journal concentrated vinegar by congelation in the following man-1, 242. Eng. ner: I freeze a whole barrel of vinegar as much as possible, then distil the remaining unfrozen vinegar in a waterbath; by which means I at first especially collect the fpirituous etherial part; the vinegar, which next comes over, I freeze again as much as possible, and afterwards purify it, by diffilling it again with three or four pounds of charcoal powder. Thus I never fail to get a very pure, fweet-fmelling, highly concentrated vinegar; the agreeable odour of which, however, may be still further improved

(1) Count Mussin-Puschin having boiled a solution of carbonat of potats on purified phosphorus, obtained carbon. This he confidered as an instance of the decomposition of carbonic acid, and as a confirmation of the experiments related in the text. See Ann. de Chim. xxv. 105.

(K) At least near the surface of the earth. Lamanon, Mongez, and the other unfortunate philosophers who accompanied La Perouse in his last voyage, have rendered it not improbable that at great heights the quantity of this gas is much smaller. They could detect none in the atmosphere at the summit of the Peak of Tenerisse. See Lamanon's Memoir at the end of La Perouse's Voyage.

Acetous improved by the addition of a proper quantity of the etherial liquor collected at the beginning of the first difillation, but which must be previously dephlegmated by two or three rectifications.

" After the distillation in the water-bath was over, that no vinegar might be loft, I used to move the retort, with the charcoal powder which remained in it, to a fand bath; and thus I obtained, by means of a strong fire, a few ounces more of a remarkably concentrated

vinegar, which was of a yellow colour.

" Having collected about ten ounces of this concentrated vinegar, I exposed it last winter in the month of December to a cold equal to -22°; in which fituation it shot into crystals from every part. I let what remained fluid drop away from the crystals into a bason placed underneath, first in the cold air, and afterwards at the window within doors. There remained in the bottle fnow-white finely foliated cryftals, closely accumulated one upon the other, and which I at first took to be nothing but ice: on placing them upon the warm flove, they diffolved into a fluid which was perfectly as limpid as water, had an uncommonly strong, highly pungent, and almost suffocating acetous smell, and in the temperature of -37° immediately congealed into a folid white crystallized mass, resembling camphor.

"After I had observed that vinegar in this state is of fuch an extraordinary strength and purity as to be in its highest degree of perfection, I took all possible pains to find out a method of obtaining all the acetous acid in

the state of glacial vinegar.

"To avoid circumlocution, I shall denote the strength of each fort of vinegar, which it was necessary for me to know in my experiments, by degrees, which I afcertain in the following manner: viz. to one drachm of vinegar I add, drop by drop, a clear folution of equal parts of carbonat of potass and water, till all at once a cloudiness or precipitation appears. Although, on the appearance of this fign, the acid is already superfaturated with the alkali, yet it feems to me to be a more accurate test for ascertaining its strength than the cessation of effervescence; for, as the point of saturation approaches, the effervescence becomes so imperceptible, that it is almost impossible to determine with precision when it is really at an end. Now, every five drops of the alkaline folution, which I find it necessary to add to the vinegar till the precipitation takes place, I reckon as one degree. Thus, for example, if a determinate quantity of vinegar requires 25 drops for that effect, I denote its strength by five degrees. This is about the strength of good distilled vinegar.

"I call that vinegar which, in confequence of its concentration, is capable of crystallizing in a great degree of cold, crystallizable vinegar; the crystals of vinegar, separated after the crystallization is completed from the remaining fluid portion, I call glacial vinegar; and, lastly, to the sluid residuum I give the name of mother-

ley of vinegar.

" From a great number of experiments, I have found that vinegar must have at least 24 degrees of concentration before it can be brought to crystallize by exposure to the most intense cold. Vinegar must be of the strength of 42 degrees at least, in order to become glacial vinegar; viz. in this state of concentration it has the property of crystallizing in a degree of cold not exceeding that in which water begins to freeze.

"I have found that charcoal, on being distilled with Acctons vinegar in a water-bath, possesses the fingular and hitherto unknown property of imbibing a certain quantity of the acetous acid in a very concentrated flate, and of retaining it fo strongly, that the acid cannot be feparated from it again but by the application of a confiderably greater degree of heat than that of boiling water. Upon this circumstance is founded the new method which I have discovered of concentrating vinegar, so as to obtain all its acid in the purest state, viz. that of a glacial vinegar.

"Let a barrel of vinegar be concentrated by freezing in the manner above described, and let the concentrated vinegar thus obtained, free from all inflammable or spirituous parts, be put into two retorts: Add to each of

them five pounds of good charcoal reduced to a fine powder, and subject them to distillation in a water bath. When no more drops of vinegar come over, put the diffilled liquor into two fresh retorts; and after adding five pounds of charcoal powder to each, proceed as before to the distillation in a water bath. In the mean while, the two first retorts are to be placed in a fandbath, that, by means of a brisk fire, the crystallizable vinegar, which is retained in the apparently dry charcoal powder, may be expelled from it. The heat must be firong enough to make the drops follow one another every two feconds; and when, in this degree of heat, 20 feconds intervene between each drop, the vinegar which has been collected must be removed; for what follows is hardly any thing else but mere water. In this manner about fix ounces and a half of cryftallizable vinegar, which is generally of the strength of between 36 and 40 degrees, may be collected from each retort. As foon as the distillation by the water-bath in the two retorts is over, the diffilled liquor is to be poured back again into the first retorts upon the charcoal powder, which remains in them, and which has been already used; and from each of these retorts the remaining crystallizable vinegar (which generally amounts to as much as the first quantity) is to be abstracted by distillation in a fand-bath. These operations may be alternately repeated till all the acid of the vinegar which had been concentrated by freezing is converted into crystallizable vinegar; or until the distilled liquor, constantly becoming weaker and weaker at every repetition of the distillation, comes over at length in the state of mere water, which, with the above mentioned quantity of charcoal powder, generally happens at the fourth or fifth distillation. Now, in order to obtain the greatest part of the pure acid contained in the crystallizable vinegar in the form of glacial vinegar, it must be set to crystallize in a great degree of cold; and the motherley must be afterwards thoroughly drained from the glacial vinegar, by letting it drop from the crystals, first in the cold, and then in the room before the window. The mother-ley may be rendered further crystallizable, by diffilling it with a little charcoal powder; the weaker part, which comes over first, being put aside. But if a person wishes to keep the crystallizable vinegar for other purposes, and without separating any glacial vinegar from it, he must distil the whole of it again with charcoal powder in a fand-bath.

"I have found by accurate experiments, that, by means of this curious process, ten pounds of vinegar concentrated by freezing to the 90th degree, may be

tous made to yield 38 ounces of crystallizable vinegar, from which 20 ounces of glacial vinegar may be obtained.

"What constitutes the excellence of this method is, that the concentration and purification are effected by one and the fame medium, viz. the charcoal powder; in consequence of which, both intentions are fulfilled at the same time.

"Last year, after much reflection, I was so happy as to find out another very effectual method of separating the acetous acid from the other substances combined with it, fo as to obtain it at once in the state of a glacial vinegar of the greatest possible strength. The separating medium which I thought of is sulphat of potals superfaturated with sulphuric acid; a salt in which, conformably to my purpose, the sulphuric acid exists in a perfectly dry and dephlegmated state.

"By means of this falt a highly concentrated gla-

cial vinegar may be obtained in the following manner:

" Let three parts of acetated foda, prepared with vinegar distilled over charcoal, and evaporated to perfect dryness, be melted in a strong heat; then pour it out, and rub it to a very fine powder. Mix this powder very accurately with eight parts of fuperfaturated fulphat of potass that has been previously well dried, and in like manner reduced to a fine powder; put the whole into a retort, and distil with a gentle heat, in such manner, that along with the drops some vapours also may be perceived to come out of the neck of the retort; but by no means so that the receiver shall be filled with these vapours. Notwithstanding the moderate heat, the vinegar comes over very fast, and the quantity of glacial vinegar, of the strength of 54 degrees, which is thus obtained, amounts to nearly two parts."

Acetous acid is capable of oxydating iron, zinc, lead,

nickel, tin, copper.

Water, Alcohol.

SECT. XII. Of Acetic Acid.

Ir acetite of copper be distilled, an acid comes over of a more pungent smell than acetous acid, capable of crystallizing, and having a stronger affinity for other bodies than acetous acid. It is called acetic acid, and is fupposed to contain a larger proportion of oxygen than acetous acid. This additional dose it is supposed to receive from the oxyd of copper, which during the process is reduced to the metallic state. It can hardly be doubted that the glacial vinegar of Lowitz, descibed in the preceding fection, is really acetic acid, though it would perhaps be difficult to explain its formation. Its affinities are the same with those of the acctous acid.

SECT. XIII. Of Oxalic Acid.

Sugar, a well known substance extracted from the sugar-cane, appears to have been used in the East at a very early period; but it made its way westward very flowly. As a medicine, it is mentioned by Dioscorides; but it was not in common use in Europe till after the 14th century.

It has been proved that fugar is composed of oxygen, Composicarbon, and hydrogen. Lavoisier concluded, from a long tion of suferies of delicate experiments, that it consists of 8 parts gar. of hydrogen, 64 of oxygen, and 28 of carbon.

From sugar, by a particular process, an acid has been Discovery obtained called oxalic acid, because it exists ready form- of exalic ed, as Scheele has proved, in the oxalis acetofella, or acid, wood forrel. At first, however, it was called the acid of Sugar, or the Saccharine acid.

As the earliest and best account of the oxalic acid was published by Bergman, he was for a long time reckoned the discoverer of it; but Mr Ehrhart, one of Scheele's intimate friends, informs us, that the world is indebted for its knwledge of this acid to that illustrious chemist *, and Hermstadt and Westrum assign the dif- * Elwert's covery to the same author †. 'The affertions of these Magazine gentlemen, who had the best opportunity of obtaining caries, 1785, accurate information, are certainly sufficient to establish Part i. the fact, that Scheele was the real discoverer of oxalicp. 54.

Bergman gives us the following process for obtaining Distinary. this acid. " Put one ounce of white fugar powdered Method of into a tubulated retort, with three ounces of ftrong ni-procuring tric acid, the specific gravity of which is to that of it. water as 1,567. When the folution is over, during which many fumes of the nitrous acid escape, let a receiver be fitted, and the liquor made to boil, by which abundance of nitrous gas is expelled. When the liquor in the retort acquires a reddish brown colour, add three ounces more of nitric acid, and continue the boiling till the fumes cease, and the colour of the liquor vanishes. Then let the contents of the retort be emptied into a wide veffel; and, upon cooling, a crystallization will take place of slender, quadrilateral prisms, which are often affixed to each other at an angle of 45°. These crystals, collected and dried on blotting paper, will be found to weigh 1' dr. 19 gr. By boiling the remaining lixivium with two ounces of nitric acid in the retort, 'till the red fumes almost disappear, and by repeating the crystallization as before, 1 dr. 13 gr. of folid acid will be obtained. If the process be repeated S 8 2

* Vauquelin, Ann. de Chim. xxii. 208.

Part

once more upon the reliduum, which has now a glutinous confiftence, with the fuccessive additions of small quantities of nitric acid, amounting in all to two ounces, a faline brown deliquescent mass will be formed, weighing half a dram, of which about a half will be lost by a farther purification. The crystals obtained thus at different times may be purified by folution and crystallization, and by digesting the last lixivium with fome nitric acid, and evaporation with the heat of the fun."

By the same process Bergman obtained it from gum arabic, alcohol, and honey; Scheele, Hermstadt, Westrum, Hoffman, &c. from a great variety of other vegatable productions; and Berthollet from a great number of animal substances.

It is of great consequence not to use too much nitric

acid, otherwife the quantity of oxalic acid will be diminished; and if a very great quantity of nitric acid be * Bergman. used, no oxalic acid will be obtained at all *. On the contrary, if too fmall a quantity of nitric acid be used, the acid obtained will not be the oxalic, but the tarta-+ Hermstadt. rous +. We think we have observed, that a considerably larger proportion of oxalic acid may be obtained by pouring nitric acid on fugar, and allowing these substances to act upon each other while cold. When the process is conducted in that manner, hardly any thing sepa-

rates but nitrous gas.

Oxalic acid is capable of crystallization, or rather it is generally obtained in that state. Its crystals are quadrilateral prisms, the ends of which often terminate in

* Bergman, ridges 1. 1. 255.

They are foluble in their own weight of boiling water: water at the temperature of 65,7° diffolves half its weight of them. The specific gravity of the solution is 1,0593 ||. One hundred parts of boiling alcohol diffolves 36 parts of these crystals; but at a mean temperature only 40 parts f. They are not eafily foluble in ether. Fixed and volatile oils diffolve them, and they may be again obtained by gentle evaporation. Too violent a heat would fublime the acid itself.

Oxalic acid has a very acrid taste when it is concentrated, but a very agreeable acid tafte when fufficiently

I Ibid. diluted with water ¶.

It changes all vegetable blues except indigo to a red. One grain of crystallized acid, diffolved in 1920 grains of water, reddens the blue paper with which fugar loaves are wrapt: one grain of it, dissolved in 3600 grains of water, reddens paper stained with turnfole *. According to Morveau, one part of the crystallized acid is sufficient to communicate a sensible acidity to 2633 parts of water +.

Its fixity is fuch, that none of it is fublimed when water containing it in folution is raifed to the boiling

When this crystallized acid is exposed to heat in an open vessel, there arises a smoke from it, which affects difagreeably the nose and lungs. The residuum is a powder of a much whiter colour than the acid had been. By this process it loses $\frac{3}{10}$ ths of its weight; but foon recovers them again on exposure to the air. When distilled, it first loses its water of crystallization, then liquifies and becomes brown; a little phlegm passes over, a white faline crust fublimes, some part of which passes into the receiver; but the greatest part of the acid is destroyed, leaving in the retort a mass inth of the whole,

which has an empyreumatic fmell, blackens fulphuric Tarra acid, renders nitric acid yellow, and diffolves in muria. Acid tic acid without alteration. That part of the acid which fublimes is unaltered. When this acid is distilled a fecond time, it gives out a white smoke, which, condensing in the receiver, produces a colourless uncrystallizable acid, and a dark coloured matter remains behind *. During all this distillation a vast quantity of ela- * Berga flic vapour makes its escape. From 279 grains of oxalic acid, Bergman obtained 109 cubic inches of gas, half of which was carbonic acid and half hydrogen. Fontana from an ounce of it obtained 430 cubic inches of gas, one-third of which was carbonic acid, the reft hydrogen. From these facts, it is evident that oxalic acid is composed of oxygen, hydrogen, and carbon; but the proportions are still unknown.

When nitric acid is frequently distilled off oxalic acid, acetous acid is produced *. The fulphuric acid, *Westran when concentrated, feems to produce the same effect. Muriatic and acetous acids diffolve oxalic acid, but without altering it +.

Oxalic acid is capable of oxydating lead, copper, iron, 150 acidin tin, bismuth, nickel, cobalt, zinc, manganese.

It does not act upon gold, filver, platinum, mercury, bodies. on other arfenic?

Oxalic acid combines with alkalies, alkaline earths, and alumina, and metallic oxyds, and forms falts known by the name of oxalats.

Its affinities, according to Bergman, are as follows: Its affini-

SECT. XIV. Of Tartarous Acid.

TARTAR, or cream of tartar as it is commonly called Difcovery when pure, has occupied the attention of chemists for of tartarous feveral centuries. Duhamel and Groffe, and after them acid. Margraf and Rouelle the Younger, proved, that it was composed of an acid united to potass; but Scheele was the first who obtained this acid in a separate state. He communicated his process for obtaining it to Retzius, who published it in the Stockholm Transactions for 1770. It consisted in boiling tartar with lime, and in decomposing the tartrite of lime thus formed by means of fulphuric acid.

This acid, by a gentle evaporation, yields crystals so its proper-irregular in their figure, that every chemist who has ies. treated of this subject has given a different description * Bergman, of them. According to Bergman, they generally con-iii. 308. fift of divaricating lamellæ *; according to Van Pack. + De Sale en, they affume oftenest the form of long pointed Espent acids prisons and Convince to Spielman and Convin prisms +; Spielman and Corvinus + obtained them in + Analesta groupes, some of them lance-shaped, others needle form- de Tartaro. ed, others pyramidal. Hence it is evifadt dent that tartarous acid also, like the four former, is composed of oxygen, hydrogen, and carbon; but the proportions are equally unafcertained.

This acid, when in crystals, dissolves readily in wa-Bergman obtained a tolution, the specific gravity he ian, of which was 1,230+. Morveau observed, however, that crystals formed spontaneously in a solution, the spe-

cific gravity of which was 1,084.

blues.

Tartarous acid does not oxydat gold, filver, platinum, lead, bifmuth, nor tin, and hardly antimony and nickel.

It combines with alkalies, alkaline earths, and alumina, and metallic oxyds, and forms falts known by the name of tartrites.

The order of its affinities is the same as that given for oxalic acid; except that, according to Lavoisier, the oxyd of filver comes before that of mercury.

SECT. XV. Of Citric Acid.

of CHEMISTS have always confidered the juice of oranges and lemons as a peculiar acid. This juice contains a quantity of mucilage and water, which render the acid impure, and fubject to spontaneous decomposition. Mr Georgius took the following method to feparate the mucilage. He filled a bottle entirely with lemon-juice, corked it, and placed it in a cellar: in four years the liquid was become as limpid as water, a quantity of mucilage had fallen to the bottom in the form of flakes, and a thick crust had formed under the cork. He exposed this acid to a cold of 23°, which froze a great part of the water, and left behind a strong and pretty bolm pure acid *. It was Scheele, however, that first pointed out a method of obtaining this acid perfectly pure. He faturated lemon-juice with lime, edulcorated the precipitate, which confifted of citric acid and lime, separated the lime from it by diluted fulphuric acid, cleared it from the fulphat of lime by repeated filtrations and evaporation; then evaporated it to the confiftence of a fyrup, and fet it by in a cool place: a quantity of cryle's stals formed, which were pure citric acid +. It exists ready formed also in the juices of the following berries: Vaccinium occicoccos, vaccinium vitis idea, prunus padus, folanum dulcamara, rosa caninat, cherries §.

Scheele advises the use of an excess of sulphuric acid, in order to insure the separation of all the lime; but, according to Dizé, this excefs is necessary for another purpose ||. A quantity of mucilage still adheres to the our- citric acid in its combination with lime, and fulphuric acid is necessary to decompose this mucilage, which, as Foureroy and Vauquelin have proved, it is capable of doing. His proof of the presence of mucilage is, that when the folution of citric acid in water, which he had obtained, was fufficiently concentrated by evaporation, it assumed a brown colour, and even became black to-

Citric wards the end of the evaporation. The crystals also were black. By repeated folutions and evaporations, this black matter was separated, and found to be carbon. Hence he concluded that mucilage had been prefent; for mucilage is composed of carbon, hydrogen, and oxygen; fulphuric acid causes the hydrogen and oxygen to combine and form water, and the carbon remains behind. It is not certain, however, as Mr Nicholfon remarks very justly +, that the fulphuric acid + Nicholfon, may not act upon the citric acid itself, and that the ibid. carbon may not proceed from the decomposition of it; at least the experiments of Mr Dizé are insufficient to prove the contrary. In that case, the smaller the excess of fulphuric acid used the better.

The crystals of citric acid are rhomboidal prisms, the Its proper-It has a very sharp acid taste, and reddens vegetable \ sides of which are inclined to each other in angles of cies. about 120 and 60 degrees, terminated at each end by four trapezoidal faces, which include the solid angles ‡. ‡ Dizé, They are not altered by exposure to the air.

An ounce of distilled water, at the temperature of the atmosphere, dissolves one ounce and two drams of crystallized citric acid; and during the solution the temperature is lowered 29,75°. Boiling water dissolves Id. 1618. twice its weight of this acid §.

Citric acid has a very acid tafte; it turns vegetable

blues to a red. It is capable of oxydating iron, zinc, tin. It does Its action not act upon gold, filver, platinum, mercury, bifmuth, on other bodies. antimony, arfenic.

It combines with alkalies, alkaline earths, and alumina, and metallic oxyds, and forms falts known by the

Fire decomposes this acid, converting it into an acidulous phlegm, carbonic acid gas, and carbonated hydrogen gas Its folution in water is also gradually decomposed, if access of air be permitted. It is evident, therefore, that this acid is also composed of oxygen, hy-

drogen, and carbon.

Scheele faid that he could not convert it into oxalie acid by means of nitric acid, as he had done feveral other acids; but Westrum affirms, that this conversion may be effected; and thinks that Scheele had probably failed from having used too large a quantity of nitric acid, by which he had proceeded beyond the converfion into oxalic acid, and had changed the citric acid into vinegar; and in support of his opinion, he quotes his own experiments: from which it appeared that, by treating fixty grains of citron acid with different quantities of nitric acid, his products were very different. Thus with 200 grains of nitric acid he got 30 grains of oxalic acid; with 300 grains of nitric acid he obtained only 15 grains of the oxalic acid; and with 600 grains of nitric acid no veftige appeared of the oxalic acid. On diffilling the products of these experiments, especially of the last, he obtained vinegar mixed with nitric acid.

The affinities of this acid are as follows *:

SECT. XVI. Of Malic Acid.

Difcovery of malic acid. 481 Method of

* Savediff

Tranf. and

Crell's An-

nals for 1785.

1 Ibid.

Scheele discovered a peculiar acid in the juices of feveral fruits, which, because it is found most abundant-

ly in apples, has been called malic acid.

He obtained it by the following process. Saturate the juice of apples with potafs, and add to the folution acetite of lead till no more precipitation ensues. Wash the precipitate carefully with a fufficient quantity of water; then pour upon it diluted fulphuric acid till the mixture has a perfectly acid tafte, without any of that fweetness which is perceptible as long as any lead remains dissolved in it; then separate the sulphat of lead, which has precipitated, by filtration, and there remains behind pure malic acid *.

This acid is contained in the berries of the barberis vulgaris, the sambucus nigra, the prunus spinosa, the

forbus aucuparia, and the prunus domestica +.

If nitric acid be distilled with an equal quantity of fugar, till the mixture affumes a brown colour (which is a fign that all the nitric acid has been abstracted from it), this substance will be found of an acid taste; and after all the oxalic acid which may have been formed is separated by lime-water, there remains another acid, which may be obtained by the following process: Saturate it with lime, and filter the folution; then pour upon it a quantity of alcohol, and a coagulation takes place. This coagulum is the acid combined with lime. Separate it by filtration, and edulcorate it with fresh alcohol; then disfolve it in distilled water, and pour in acetite of lead till no more precipitation enfues. The precipitate is the acid combined with lead, from which it may be separated by diluted sulphuric acid. It possesses all the properties of malic acid ‡. This acid, therefore, may be obtained from fugar; and it may be converted into oxalic acid, by diffilling off it the

§ Hermstadt, proper quantity of nitric acid f.

This acid bears a strong resemblance to the citric, but

differs from it in the folloring particulars:

1. The citric acid shoots into fine crystals, but this acid does not crystallize.

2. The falt formed from the citric acid with lime is almost insoluble in boiling water; whereas the salt made with malic acid and the same basis is readily soluble by boiling water.

when diluted with water; whereas citric acid does not alter any of these solutions.

3. Malic acid feems to have a less affinity than citric acid for lime; for when a folution of lime in the former acid is boiled one minute with a felt formed from volatile alkali and citric acid, a decomposition takes place, and the latter acid combines with the lime and is precipitated.

The malic acid combines with alkalies, alkaline earths, Its c and alumina, and metallic oxyds, and forms falts known natio

by the name of malats.

Its affinities have not yet been afcertained.

SECT. XVII. Of Ladic Acid.

IF milk be kept for some time it becomes four. The acid which then appears in it was first examined by Scheele, and found by him to have peculiar properties. It is called latic acid. In the whey of milk this acid is mixed with a little curd, foine photphat of lime, fugar of milk, and mucilage. All these must be separated before the acid can be examined. Scheele accomplished

this by the following process:

Evaporate a quantity of four whey to an eighth part, Met and then filtrate it: this separates the cheefy part. Sa-obta turate the liquid with lime-water, and the phosphat of laction lime precipitates. Filtrate again, and dilute the liquid with three times its own bulk of water; then let fall into it oxalic acid, drop by drop, to precipitate the lime which it has diffolved from the lime-water: then add a very small quantity of lime-water, to see whether too much oxalic acid has been added. If there has, oxalat of lime immediately precipitates. Evaporate the folution to the confishence of honey, pour in a sufficient quantity of alcohol, and filtrate again; the acid paffes through diffolved in the alcohol, but the fugar of milk and every other substance remains behind. Add to the folution a small quantity of water, and distil with a small heat, the alcohol paffes over, and leaves behind the lactic acid diffolved in water *.

This acid is incapable of crystallizing: when evapo- Stockhoo rated to dryness, it deliquesces again in the air +.

When distilled, water comes over first, then a weak 1700 acid refembling the tartarous, then an empyreumatic oil 485 mixed with more of the same acid, and lastly carbonic tte prop acid and hydrogen gas-there remains behind a fmall ties, quantity of coal t.

The combinations which this acid forms with alka-Combin lies, earths, and metallic oxyds, are called lactats.

Its affinities, according to Bergman, are as follows:

Barytes,

Potafs, ties. Soda, Ammonia, Lime, Magnefia, Alumina. Jargonia €? & Vangue Metallic oxyds as in fulphuric acid. Chim. X Water,

SECT. XVIII. Of Saccholattic Acid.

Gallie

e mass is obtained. If this be dissolved in water, clarified with the white of eggs, filtrated, and evaporated to the confistence of a syrup, it deposits on cooling a number of brilliant, white, cubic crystals, which have a sweet taste, and for that reason have been called fugar of milk. Fabricius Bartholet, an Italian, was the first European who mentioned this sugar. He described it in his Encyclopædia Hermetico dogmatica, published at Boulognia in 1619; but it feems to have been known in India

long before that period. After Mr Scheele had, obtained oxalic acid from fugar, he wished to examine whether the sugar of milk would furnish the same product. Upon four ounces of pure fugar of milk, finely powdered, he poured 12 ounces of diluted nitric acid, and put the mixture in a large glass retort, which he placed in a fand bath. A violent effervescence ensuing, he was obliged to remove the retort from the fand-bath till the commotion ceased. He then continued the distillation till the mixture became yellow. As no crystals appeared in the liquor remaining in the retort, after standing two days he repeated the distillation as before, with the addition of eight ounces of nitric acid, and continued the operation till the yellow colour, which had disappeared on addition of the nitrous acid, returned. The liquor in the retort contained a white powder, and when cold was observed to be thick. Eight ounces of water were added to dilute this liquor, which was then filtrated, by which the white powder was feparated; which being edulcorated and dried weighed 71 dr. The filtrated folution was evaporated to the confistence of a fyrup, and again subjected to distillation, with four ounces of nitric acid as before; after which, the liquor, when cold, was observed to contain many small, oblong, four crystals, together with some white powder. This powder being separated, the liquor was again distilled with more nitric acid as before; by which means the liquor was rendered capable of yielding crystals again; and by one distillation more, with more nitrous acid, the whole of the liquor was converted into crystals. These crystals, added together, weighed five drams; and were found, upon trial, to have the properties of the oxalic acid.

Mr Scheele next examined the properties of the white powder, and found it to be an acid of a peculiar nature; he therefore called it the acid of fugar of milk. It is

now called the faccholactic acid.

According to Scheele, it is foluble in 60 parts of its weight of boiling water; but Meffrs Hermstadt* and Morveau + found, that boiling water only diffolved Toth part: it deposited about ith part on cooling in the form of crystals 1.

The solution has an acid taste, and reddens the infufion of turnfole f. Its specific gravity, at the tempe-

beau, rature of 53,7°, is 1,0015 ||.

When distilled, it melts very readily, becomes black, and frothes; a brown falt fublimes into the neck of the retort, which has the odour of a mixture of amber and benzoin, having an acid taste, easily soluble in alcohol,

with greater difficultly in water, and burning in the fire with a flame. There passes into the receiver a brown liquid, having some of this salt dissolved in it: There remains behind a coal ¶, which Hermstadt found to contain ¶ Scheele, a finall quantity of lime. Concentrated fulphuric acid di-ibid. stilled on this falt becomes black, frothes, and decomposes it *.

Mr Hermstadt of Berlin had made similar experiments on fugar of milk at the fame time with Scheele, and with Hermstadt fimilar refults; but he concluded, that the white pow-disprove its der which he obtained was nothing else than oxalat of existence. lime with excefs of acid, as indeed Scheele himself did at first. After he became acquainted with Scheele's conclusions, he published a paper in defence of his own opinion; but his proofs are very far from establishing it, or even rendering its truth probable. He acknowledges himself, that he has not been able to decompose this supposed falt: he allows that it possesses properties distinct from the oxalic acid; but he ascribes this difference to the lime which it contains; yet all the lime which he could discover in 240 grains of this falt was only 20 grains; and if the alkali which he employed was a carbonat (as it probably was), these 20 must be reduced to 11. Now Morveau has shewn, that oxalic acid, containing the fame quantity of lime, exhibits very different properties. Besides, this acid, whatever it is when united with lime, is separated by the oxalic, and must therefore be different from it, as it would be abfurd to fuppose that an acid could displace itself *. The fac- * Morveau; cholactic acid must therefore be considered as a distinct Method. 1. acid, as it possesses peculiar properties.

Its compounds with alkalies, earths, and metallic

oxyds, are denominated faceholats.

Its affinities, according to Bergman, are as follows: pounds and affinities.

Lime, Barytes, Magnesia, Potafs, Soda. Ammonia, Alumina, Targonia †? Metallic oxyds as in fulphuric acid, Chim. xxii. Water,

+ Vauqueling Ann. de

SECT. XIX. Of Gallic Acid.

· Alcohol.

THERE is an excrescence, known by the name of nut Nut galls. gall, which grows on fome species of oaks. This substance contains a peculiar acid, called from that circumflance gallic acid, the properties of which were first examined with attention by the commissioners of the academy of Dijon; and the refult of their experiments was published in 1777, in the third volume of their Elements of Chemistry. In these experiments, however, they employed the infusion of galls, in which the acid is combined with the tanning principle (M). It was referved for Scheele to obtain it in a state of purity.

(M) A fubflance lately discovered by French chemists, which exists also in oak-bark, and every other body which may be substituted for that bark in the operation of tanning. It resembles the resins in many properties; but its diftinguishing property is that of forming with glue a compound infoluble in water. When a little of the decoction of glue is dropped into an infusion of nut-galls, a white curdy precipitate is inflantly seen: This is the tanning principle combined with glue. The name tanning principle has been applied to it, because tanning confilts in combining this principle with Jkins, by which they are converted into leather.

* Id. ibid.

Gallic Acid.

Discovery of gallic a-

1786.

495

He observed, in an infusion of galls made with cold water, a fediment, which proved on examination to have a crystalline form and an acid taste. By letting an infusion of galls remain a long time exposed to the air, and removing now and then the mouldy skin which formed on its surface, a large quantity of this sediment was obtained; which being edulcorated with cold water, rediffolved in hot water, filtrated and evaporated very * Stockholm flowly, yielded an acid falt in crystals as fine as fand *.

There is a shorter method of obtaining this acid in

a still purer state than Scheele obtained it.

Pour fulphuric ether on a quantity of powdered galls, Method of and allow it to remain a few hours; by which time it obtaining becomes coloured. Put this tincture into a retort, and distil off the other with a small heat. The residuum possesses the colour and brittleness of a resin, and has all the characters of Rouelle's refiduous extract; it does not attract moisture from the atmosphere. Diffolve it in its own weight of water, and add fulphuric acid, drop by drop, till the liquor has become of a manifeftly acid taste. It causes a white precipitate, which becomes coloured, and is immediately rediffolved. At the end of some hours a refinous matter will have precipitated. Decant off the fluid, dilute it with half its weight of water, filtrate and evaporate it to 1/4 ths in a moderate heat; add pure barytes till the liquor is no longer capable of decomposing muriat of barytes; then filtrate it again; and on evaporation in a moderate heat small white prismatic crystals of gallic acid are formed on the

+ Mr J. J. sides of the vessel +. It appears from the experiments of Deyeux, that the Dec. 1791. Substance extracted from nut-galls by ether does not differ much from the extract by water ‡. Probably, then, Chim. xvii. the only reason for employing ether is the small heat

necessary for evaporating it.

There is still another method of obtaining this acid. Distil nut-galls in a strong heat, a white substance sublimes, which crystallizes in the form of needles: This is gallic acid. If the crystals are impure, they may be purified by a fecond sublimation: but the heat must not be too violent, otherwise the crystals will melt into a brown mass *. This process was discovered by

Proust's Scheele. But the most elegant method of obtaining gallic acid

is that of Mr Proust. When a folution of muriat of tin is poured into an infusion of nut-galls, a copious yellow precipitate is instantly formed, consisting of the tanning principle, combined with the oxyd of tin. After diluting the liquid with a sufficient quantity of water to separate any portion of this precipitate which the acids might hold in folution, the precipitate is to be separated by filtration. The liquid contains gallic acid, muriatic acid and muriat of tin. To separate the tin, a quantity of fulphurated hydrogen gas is to be mixed with the liquid. Sulphuret of oxyd of tin is precipitated under the form of a brown powder. The liquid is then to be exposed for some days to the light, covered with paper, till the superfluous sulphurated hydrogen gas exhales. After this, it is to be evaporated to the proper degree of concentration, and put by to cool. Crystals of gallic acid are deposited. These are to be separated

by filtration, and washed with a little cold water. The

evaporation of the rest of the liquid is to be repeated

till all the gallie acid is obtained from it +.

The gallic acid thus obtained has a very acid taffe, and reddens vegetable colours. It is foluble in 11 parts of boiling water, and in 12 parts of water at the temperature of the atmosphere. Alcohol dissolves one is it fourth of its weight of this acid at the temperature of ties. the atmosphere. When boiling hot, it dissolves a quantity equal to its own weight.

When placed upon burning coals, gallic acid takes fire, and at the same time diffuses a very strong odour, which has fomething aromatic in it. When strongly heated, it melts, boils, becomes black, is diffipated, and leaves a quantity of charcoal behind it. When diftilled, a quantity of oxygen gas is difengaged, an acid liquor is found in the receiver, with some gallie acid not decomposed, and there remains in the retort a quantity of earbon. If what has paffed into the receiver be again distilled, more oxygen gas is obtained, some gallic acid still sublimes, and a quantity of carbon remains in the retort. By repeated diffillations the whole of the acid may be decomposed. This decomposition may be more easily accomplished by distilling repeatedly a solution of gallic acid in water. The products are oxygen gas, charcoal, and an acid liquor.

From these experiments, Mr Deyeux, who perform-lts co ed them, has concluded, that gallic acid is composed of lition. oxygen, and a much larger proportion of carbon than enters into the composition of carbonic acid. But this conclusion is not warranted by the analysis; for Mr Deyeux did not find that the quantity of oxygen gas and carbon obtained was equal to that of the gallic acid decomposed: and in the acid liquor_which came over, there evidently existed a quantity of water, which doubtless was formed during the distillation. Scheele, by treating gallic acid with nitric acid in the usual manner, converted it into oxalic acid. Now it is certain, that oxalic acid contains hydrogen as well as carbon. It cannot be doubted, then, that gallic acid is compofed of oxygen, hydrogen, and carbon, in proportions not yet ascertained. But Mr Deyeux has proved, that the quantity of carbon is very great, compared with that of the hydrogen.

Gallic acid combines with alkalies, earths, and metallic oxyds, and forms compounds, known by the name

of gallats.

Its affinities have not yet been determined; but oxyd of iron feems to have a stronger affinity for it than for any other substance; for gallic acid is capable of taking it from every other acid. In consequence of this property, the infusion of galls is employed to detect the presence of iron in any liquid. As soon as it is poured in, if iron be prefent, a black or purple colour is produced.

SECT. XX. Of Benzoic acid.

Benzoin or benjamin (as it is sometimes called) is a Benzoin kind of refin brought from the East indies; obtained, according to Dr Dryander, from the styrax benzoe, a tree which grows in the island of Sumatra. This subftance confifts partly of a peculiar acid, described as long ago as 1608 by Blaife de Vigenere, in his Treatife on Fire and Salt, under the name of flowers of benzoin, because it was obtained by sublimation. acid, which is now called the benzoic acid, may be fublimed from benzoin by heat; or it may be obtained by Scheele's

method.

* Ibid.

+ Ibid. EEV. 225. inic Scheele's process, which has been described in the ar-

ticle CHEMISTRY (Encycl.).

rties which diftinguishes benzoin. Its taste is not acid, but zoic sweetish and very pungent *. It hardly affects the inacid, and makes it give out a strong odour, which excites coughing. When exposed to the heat of the blow-pipe in a filver spoon, it melts, becomes as fluid as water, and evaporates without taking fire. It only burns when in contact with flame, and then it leaves no refiduum behind. When thrown upon burning coals, it rifes in a white smoke. When allowed to cool after being melted, it hardens, and a radiated crust forms on its surface 1.

It fuffers no other alteration in the air than lofing the little of the odour of benzoin which remained to

Cold water dissolves no sensible quantity of it; but it is foluble enough in hot water: 480 grains of boiling water diffolve 20 grains of it; 19 of these are deposited, when the water cools, in long, slender, flat, fea-

ther-like crystals +.

Concentrated fulphuric acid diffolves it without heat or any other change, except becoming fomewhat brown: when water is poured into the folution, the benzoic acid separates and coagulates on the surface without any alteration ‡. Nitric acid prefents precifely the fame phenomena, and also the sulphurous and nitrous acids. Neither the muriatic, the oxy-muriatic, nor the phosphoric acids diffolve it. The acetous, formic, and febacic acids, when hot, diffolve it precifely as water does; but it crystallizes again when these acids cool ||.

Alcohol dissolves it copiously, and lets it fall on the

addition of water *.

Little is known respecting its base.

It combines with alkalies, earths, and metallic oxyds, sand and forms falts, known by the name of benzoats.

Its affinities, from the experiments of Trommsdorf,

appear to be as follows:

White oxyd of arfenic, Potafs, Ammonia, Barytes, Lime, Magnefia, Alumina, Jargonia ‡? Water, Alcohol,

SECT. XXI. Of Succinic Acid.

Amber is a well-known brown, transparent, inflammable body, pretty hard, and susceptible of polish, found at some depth in the earth, and on the sea-coast of several countries. It was in high estimation among the ancients both as an ornament and a medicine.-When this fubstance is distilled, a volatile salt is obtained, which is mentioned by Agricola under the name of falt of amber; but its nature was long unknown. Boyle lea- was the first who discovered that it was an acid *. From fuccinum, the Latin name of amber, this acid has received the appellation of fuccinic acid.

SUPPL. VOL. I. Part I.

It is obtained by the following process: Fill a re. Camphoric tort half way with powdered amber, and cover the pow- Acid-Benzoic acid has little or none of the peculiar odour der with a quantity of dry fand; lute on a receiver, and diffil in a fand-bath without employing too much Method of heat. There passes over first an insipid phlegm; then obtaining fusion of violets; but it reddens that of turnfole, espe- a weak acid, which, according to Scheele, is the ace-fuccinic acid. Heat volatilizes this tous †; then the succinic acid attaches itself to the † Bergman's neck of the retort; and if the distillation be continued, Notes on there comes over at last a thick brown oil, which has Scheffier. an acid tafte.

> The fuccinic acid is at first mixed with a quantity of oil. Perhaps the best method of purifying it is that recommended by Pott, to dissolve it in hot water, and to put upon the filter a little cotton, previously moiftened with oil of amber; this substance retains most of the oil, and allows the solution to pass clear. The acid is then to be crystallized by a gentle cvaporation. And this process is to be repeated till the acid be quite pure. The crystals are white, shining, and of a foliated triangular prilmatic form: they have an Its properacid taile, but are not corrosive: they redden tincture ties, of turnfole; but have little effect on that of violets.

They fublime when exposed to a confiderable heat, but not at the heat of a water-bath. In a fand bath they melt, and then sublime and condense in the upper part of the veffel; but the coal which remains shews

that they are partly decomposed *. One part of this acid diffolves in 96 parts of water at the temperature of 50°, according to Spielman t, Inft. Chema in 24 parts at the temperature of 52°, and in 2 parts xii. of water at the temperature of 212°, according to Stockar de Neuforn +; but the greatest part crystal + De Succilizes as the water cools. According to Roux, how-no. ever, it still retains more of the acid than cold water is capable of diffolving 1. ibid, p. 72.

240 grains of boiling alcohol diffolve 177 of this acid; but crystals again shoot as the solution cools *.

The combinations of this acid are called fuccinats. Its component parts are still unknown.

tions and Its affinities, according to Morveau, are as follows: affinities.

SECT. XXII. Of Camphoric Acid.

CAMPHOR is a well-known white crystalline substance, Camphor. of a strong taste and smell, obtained from a species of laurel in the East Indies; and Mr Proust has shown that feveral volatile oils contain a confiderable quantity of it *. It is so volatile, that it cannot be melted in * Ann. de open veffels, and so inflammable, that it burns even on Chim. iv. the furface of water.

When camphor is fet on fire in contact with oxygen gas, it burns with a very brilliant flame; much caloric is disengaged, water is formed, the inner surface of the vessel is covered with a black matter, which is undoubtedly carbon, and a quantity of carbonic acid gas is also

Camphoric produced +. Hence it follows, that it is composed of hydrogen and carbon, at least principally.

Ann. de clay be mixed together, by means of alcohol, in a mor-If one part of camphor and fix parts of pulverised Ctim. xxiii. tar, the mixture made up into balls, and when dry put into a retort, and distilled by a moderate heat - a quan-

tity of oil comes over, and there remains in the retort a black substance, which consists of the clay intimately mixed with a quantity of carbon. If the fire be not cautiously managed, a quantity of camphor also sublimes. By this process, camphor is decompounded, and separated into oil and carbon.

122,248 parts of camphor

produced 45,856 parts of oil 30,571 of carbon.

Total 76,427 45,821 Loss

Carbonated hydrogen gas and carbonic acid were

\$ Ibid. also formed t. 507 Oil of cam-

The oil obtained has the following properties:

It has a sharp caustic taste, and leaves upon the tongue a sense of coldness. It has an aromatic odour, approaching to that of thyme or rolemary. Its colour is a golden yellow.

When exposed to the air, it partly evaporates, and there remains a thick brown matter with a sharp bit-

terish taste, which at last also evaporates.

With alkalies, it forms a foap, which possesses all the characters of soaps made with volatile oils.

Alcohol diffolves it entirely; and when water is added to the folution it becomes milky, but no precipitate is produced 1.

Ann. de Clim. xxiii.

159.

1785.

4 Ann. de

phor.

These properties show that this is a volatile oil, and consequently it is probable that camphor is composed of volatile oil and carbon.

508 Camphoric Mr Kosegarten, by distilling nitric acid off camphor eight times successively, obtained an acid in crystals*, to ten, de Cam- which the name of camphoric acid has been given.

His experiments have been repeated by Mr Bouillon phore, &c. La Grange. He mixed together 122,284 parts of camphor with 489,136 parts of nitric acid of the specific gravity 1,33, and distilled them. Much nitrous and carbonic acid gas were disengaged, and part of the camphor was fublimed; but part was converted into an acid. He returned the fublimed camphor into the retort, poured on it the same quantity of nitric acid as at first, and distilled again. This process he repeated till the whole camphor was acidified †. The quantity of camphoric acid obtained amounted to 53,498. The

quantity of nitric acid was 2114,538. Camphoric acid thus obtained is in snow-white cry-Its proper-

stals, of the form of parallelopipedons *. * Kofegar-These crystals effloresce in the air ‡.

Camphoric acid has a flightly acid bitter tafte, and a La Grange. smell like that of faffron.

It reddens vegetable colours.

It is foluble in 200 parts of cold water, according to Kosegarten; in 96 parts of water at the temperature of 60, according to La Grange. Boiling water dif-

& Kofegar- folves Tath of its weight J. According to Kofegarten, it is infoluble in alcohol; according to La Grange, alcohol dissolves it, and when the folution is left in contact with the air of the atmo-Chim. xxvii. sphere, the acid crystallizes. It is not precipitated from its folution in alcohol by the addition of water *.

When this acid is placed on ignited coals, it emits a Suber dense aromatic sume, and is entirely distipated. By a gentler heat, it melts, and is sublimed. If it be put into a heated porcelain tube, and oxygen gas be paffed through it, the acid does not undergo any change, but

By mere distillation, it first melts and then sublimes: by which process its properties are in some respect changed. It no longer reddens the tincture of turnfol, but acquires a brisk aromatic smell; its taste becomes less penetrating, and it is no longer soluble either in water or the fulphuric and muriatic acids. Heated nitric acid turns it yellow and diffolves it. Alcohol likewife diffolves it; and if this folution be left in contact with the air of the atmosphere, it crystallizes.

Camphoric acid does not produce any change in fulphur; alcohol and the mineral acids totally diffolve it; and so likewife do the volatile and the fat oils.

Camphoric acid does not precipitate lime from lime. water. It produces no change on the folution of indigo in fulphuric acid.

It forms combinations with the alkalies, earths, and It's com metallic oxyds, which are called camphorats.

Its affinities, as far as afcertained by La Grange, are affinities as follows *. Chim. XX

Lime. Potass, Soda, Barytes, Ammonia. Alumina, Magnesia,

SECT. XXIII. Of Suberic Acid.

CORK, a fubstance too well known to require any Discover description, is the bark of a tree which bears the same of suberi name. By means of nitric acid, Brugnatelli converted acid. it into an acid +, which has been called the fuberic acid, + Crell's from Suber, the Latin name of the cork tree. Several Annali, chemists affirmed that this acid was the oxalic, because 1787. it possessed feveral properties in common with it. These assertions induced Buillon La Grange to undertake a set of experiments on suberic acid. These experiments, which have been published in the 23d volume of the Annales de Chimie, completely establish the peculiar nature of suberic acid, by shewing that it possesses properties different from those of every other acid.

To prepare it, a quantity of found cork grated down Methods small is to be put into a retort, fix times its weight of preparing nitric acid of the specific gravity 1,261 poured upon it. it, and the mixture distilled by means of a gentle heat. Red vapours are immediately discharged; the cork swells up and becomes yellow, and as the distillation advances, it finks to the bottom, and its furface remains frothy. If that froth does not form properly, it is a proof that fome part of the cork has escaped the action of the acid. In that case, after the distillation is pretty far advanced, the acid which has passed into the receiver is to be poured back into the retort, and the distillation continued till no more red vapours can be perceived; and then the retort is to be immediately taken out of the fand-bath, otherwife its contents would become black and adhere to it. While the matter contained in the retort is hot, it is to be poured into a glass veffel, placed upon a fand-bath over a gentle fire, and conftantly ftirred with a glass rod. By this means it becomes

gradually

ic gradually thick. As foon as white vapours, exciting a tickling in the throat, begin to disengage themselves, the vessel is removed from the bath, and the mass continually stirred till it is almost cold.

By this means an orange coloured mass is obtained of the confishence of honey, of a strong and sharp odour while hot, but having a peculiar aromatic fmell when

On this mass twice its weight of boiling water is to be poured, and heat applied till it becomes liquid; and then that part of it which is infoluble in water is to be separated by filtration (N). The filtered liquor becomes muddy; on cooling it deposits a powdery sediment, and a thin pellicle forms on its furface. The fediment is to be separated by filtration, and the liquor reduced to a dry mass by evaporating in a gentle heat. This mass is fuberic acid. It is still a little coloured, owing to some accidental mixture, from which it may be purified either by faturating it with potals and precipitating it by means of an acid, or by boiling it along with charcoal powder.

Suberic acid thus obtained is not crystallizable, but when precipitated from potass by an acid it assumes the form of a powder; when obtained by evaporation it

forms thin irregular pellicles.

Its taste is acid and slightly bitter; and when dissolved in a small quantity of boiling water it acts upon the

throat, and excites coughing.

It reddens vegetable blues; and when dropped into a folution of indigo in fulphuric acid (liquid blue, as it is called in this country), it changes the colour of the folution, and renders it green.

Water at the temperature of 60° or even 70° dissolves

only 1 part of its weight of suberic acid, and if the acid be very pure, only +124th part: boiling water, on the contrary, diffolves half its weight of it.

When exposed to the air, it attracts moisture, espe-

cially if it be impure.

When exposed to the light of day, it becomes at last brown; and this effect is produced much sooner by the

direct rays of the fun.

When heated in a matrass, the acid sublimes, and the infide of the glass is surrounded with zones of different colours. If the fublimation be stopped at the proper time, the acid is obtained on the fides of the vessel in fmall points formed of concentric circles. When exposed to the heat of the blow-pipe on a spoon of platinum, it first melts, then becomes pulverulent, and at last sublimes entirely with a smell resembling that of sebacic acid (o).

It is not altered by oxygen gas:-the other acids do not diffolve it completely. Alcohol developes an aromatic odour, and an ether may be obtained by means

of this acid.

It converts the blue colour of nitrat of copper to a green; the sulphat of copper also to a green; green sulphat of iron to a deep yellow; and fulphat of zinc to a golden yellow (P).

It has no action either on platinum, gold, or nickel; Its action but it oxydates filver, mercury, copper, lead, tin, iron, on other bifmuth, arfenic, cobalt, zinc, antimony, manganese, and bodies.

molybdenum. With alkalies, earths, and metallic oxyds, it forms

compounds known by the name of fuberats.

Its affinities are as follows (Q):

Its affinities

(N) When this fubstance is put into a matrafs, water poured on it, and heat applied, it melts; and when the veffel is taken from the fire and allowed to cool, one part of it, which is of the confiftence of wax, fwims on the furface of the water, and another part precipitates to the bottom of the veffel, and assumes the appearance of a whitish magma. When this magma is separated by siltration, and washed and dried, a white tasteless powder is obtained, mixed with ligneous threads, foluble in acids and alkalies.

(o) An acid which shall be afterwards described.

(P) Owing perhaps to the presence of a little iron in the sulphat.

(Q) The place which the suberic acid occupies in the affinities of the alkalies, earths, and metallic oxyds, as far as this subject has been investigated by Bouillon La Grange, will appear by the following tables:

Mr Buillon La Grange, to whom we are indebted for all the facts relative to this acid, supposes that it is Its composi-composed of oxygen, hydrogen, and carbon: but Mr Jameson, in contequence of the result of a series of experiments which he made on charcoal, has been led to suspect that it consists entirely of carbon and oxygen. He found that, by the action of nitric acid upon charcoal, a brown, bitter, deliquescent mass was formed, foluble in water, alcohol, and alkalies, and which emitted, particularly when heated, a very fragrant odour. This matter was more or less foluble in water according to the time that it had been exposed to the action of the acid. When the nitric acid uled was concentrated, and confiderable in quantity, part of the charcoal was converted into an acid, which poffeffed the characters of + Fameson's the suberic +.

Mineralogy

These facts are curious, and may extend our knowof Shetland ledge of the nature of vegetable acide, but they are inand Arran, fufficient to prove the absence of hydrogen in suberic acid, because charcoal cannot easily be procured perfectly free from hydrogen, and because several of the properties of suberic acid indicate the presence of hydrogen in it, its becoming brown, for inflance, when exposed to the light. Mr Jameson has observed, that the acid which exists ready formed in peat possesses the properties of suberic acid

SECT. XXIV. Of Laccic Acid.

Difcovery of white lac.

ABOUT the year 1786, Dr Anderson of Madras mentioned, in a letter to the governor and council of that place, that nefts of infects, refembling small cowry shells, had been brought to him from the woods by the natives, who eat them with avidity. These supposed nests he foon afterwards discovered to be the coverings of the females of an undefcribed species of coccus, which he shortly found means to propagate with great facility on feveral of the trees and shrubs growing in his neighbourhood (R).

On examining this fubstance, which he called white lac, he observed in it a very considerable resemblance to bees wax; he noticed also, that the animal which fecretes it provides itself by some means or other with a fmall quantity of honey, refembling that produced by our bees; and in one of his letters he complains, that

the children whom he employed to gather it were Laco tempted by its sweetness to eat so much of it as materially to reduce the produce of his crop. Small quantities of this matter were fent into Europe in 1789, both in its natural state and melted into cakes; and ih 1793 Dr Pearson, at the request of Sir Joseph Banks, undertook a chemical examination of its qualities, and his experiments were published in the Philosophical Transactions for 1794.

A piece of white lac, from 3 to 15 grains in weight, Its analy is probably produced by each infect. These pieces are of a grey colour, opaque, rough, and roundish. When white lac was purified by being strained through muslin, it was of a brown colour, brittle, hard, and had a bitterish taste. It melted in alcohol, and in water of the temperature of 145°. In many of its properties it refembles bees wax, though it differs in others; and Dr Pearson supposes that both substances are composed of the same ingredients, but in different proportions.

I'wo thousand grains of white lac were exposed in fuch a degree of heat as was just fufficient to melt them. As they grew fort and fluid, there oozed out 550 grains of a reddish watery liquid, which smelled like newly baken bread (s). To this liquid, Dr Pearson has given the name of laccic acid +.

It possesses the following properties:

Tranfl. of It turns paper stained with turnsole to a red colour. the Chem After being filtered, it has a flightly faltish taste with ture. bitterness, but is not at all four.

When heated, it finells precifely like newly baken hot Properties bread.

On flanding, it grows fomewhat turbid, and depofits a small quantity of sediment.

Its specific gravity at the temperature of 600 is 1,025

A little of it having been evaporated till it grew very turbid, afforded on standing small needle shaped crystals in mucilaginous matter.

Two hundred and fifty grains of it were poured into a very small retort and distilled. As the liquor grew warm, mucilage like clouds appeared; but as the heat increafed they disappeared again. At the temperature of 200°, the liquor distilled over very fast: A small quantity of extractive matter remained behind. The diffilled liquor while hot smelled like newly baken bread, and was perfectly transparent and yellowish. A shred of paper stained with turnsole, which had been put into the receiver, was not reddened; nor did another which had been immerfed in a tolution of fulphat of iron, and also placed in the receiver, turn to a blue colour upon being moistened with the solution of potals (T).

About

OXYD OF IRON. OXYD OF BISMUTH. OXYD OF ARSENIC. Sulphuric, Muriatic, Nitric acid, Suberic. Suberic. Suberic, COBALT and ZINC the fame with arfenic.

(R) The Chinese collect a kind of wax, which they call pe-la, from a coccus, deposited for the purpose of breeding on several shrubs, and manage it exactly as the Mexicans manage the cochineal insect. It was the knowledge of this that induced Dr Anderson to attempt to propagate his insect.

(s) The same liquid appears on pressing the crude lac between the singers; and we are told, that when newly gathered it is replete with juice.

(T) A proof that the acid was not the pruffic.

About one hundred grains of this diffilled liquid being evaporated till it grew turbid, after being fet by for a night, afforded acicular crystals, which under a lens appeared in a group not unlike the umbel of parfley. The whole of them did not amount to the quarter of a grain. They tasted only bitterish.

Another 100 grains being evaporated to dryness in a very low temperature, a blackish matter was left behind, which did not entirely disappear on heating the spoon containing it very hot in the naked fire; but on leating oxalic acid to a much less degree, it evaporated

and left not a trace behind.

Carbonat of lime dissolved in this distilled liquid with effervescence. The solution tasted bitterish, did not turn paper stained with turnsole red, and on adding to it carbonat of potass a copious precipitation ensued. A little of this solution of lime and of alkali being evaporated to dryness, and the residuum made red hot, nothing remained but carbonat of lime and carbonat of potass.

This liquid did not render nitrat of lime turbid, but it produced turbidness in nitrat and muriat of barytes.

To five hundred grains of the reddift-coloured liquor obtained by melting white lac, carbonat of foda was added till the efferveicence ceafed, and the mixture was neutralifed; for which purpofe three grains of the carbonat were necessary. During this combination a quantity of mucilaginous matter, with a little carbonat of lime, was precipitated. The faturated folution being filtrated and evaporated to the due degree, afforded on thanding deliquescent crystals, which on exposure to fire left only a retiduum of carbonat of soda.

Lime-water being added to this reddiff-coloured liquor produced a light purple turbid appearance; and

on standing there were clouds just perceptible.

Sulphuret of lime occasioned a white precipitation, but no sulphurated hydrogen gas was perceptible by the smell.

Tincture of galls produced a green precipitation.

Sulphat of iron produced a purplish colour, but no precipitation; nor was any precipitate formed by the addition first of a little vinegar, and then of a little potafs, to the mixture.

Acetite of lead occasioned a reddish precipitation,

which rediffolved on adding a little nitric acid.

Nitrat of mercury produced a whitish turbid liquor.

Oxalic acid produced immediately the precipitation of white acicular crystals, owing probably to the prefence of a little lime in the liquid.

Tartrite of potais produced a precipitation not unlike what takes place on adding tartarous acid to tartrite of potals (u); but it did not diffolve again on

adding potafs.

Such were the properties of this acid discovered by Dr Pearton. Its destructibility by fire, and its affording carbon, distinguish it from all the acids described in this article before the acetous; and its peculiar smell when heated, its precipitating tartrite of potass without forming tartar, its bitterish taste, and its being con-

About one hundred grains of this distilled liquid be-verted into vapour at the temperature of 200°, distin-Pyro u-cous A id.

SECT XXV. Of Pyromucous Acid.

* Phil. Tranf.1794.

Pyromucous (v) acid is procured by diffilling fugar P. 383. or any of the fweet juices. As they foam very much, Method of the retort should be large, and seven eighths of it empty obtaining A prodigious quantity of carbonic acid and carbonated pyromuhydrogen gas is difengaged: A very thin light coal re-cons acid. mains behind in the retort. Morveau found the glass of the retort attacked. The quantity of fugar diffilled was 2304 grains; the coal weighed 982 grains There were 428 grains of a brown liquor in the receiver, confifting mostly of an acid phlegm. This redistilled gave 313 grains of a liquor almost limpid, the specific gravity of which was 1,011; at the temperature of 77°. It reddened blue paper. This acid may be concentrated by freezing, or by combining it with some base, potafs, for inftance, and decomposing the compound by a stronger acid, as, for example, the sulphuric.

It has a very sharp taste. When exposed to heat in Its properopen vessels, it evaporates, leaving a brown spot. Dif-tics,

tilled in close vessels, it leaves charcoal behind it.

It does not diffolve gold as Schrickel and Lemery

and feveral other chemists affirmed.

It does not attack filver nor mercury, nor even their oxyds †. It corrodes lead, and forms flyptic and long † Schrickes, crystals. Copper forms with it a green folution: With iron it forms green crystals; with antimony and zinc greenish folutions.

The compounds which it forms are called pyromucites. Combina-Its affinities, according to Morveau, are as follows: tions and

SECT. XXVI. Of Pyro-lignous Acid.

It is well known that the fmoke of burning wood is Method of exceedingly offensive to the eyes: And chemists have obtaining long ago observed, that an acid might be obtained by pyrolig-nous acid.

It is to Mr Goettling, however, and to the Dijon academicians, who repeated his experiment, that we are indebted for what knowledge we possess of the peculiar properties of this acid, which, because it is obtained from wood by means of fire, has been called the pyrolignous acid (w). It appears to be the same from what ever kind of wood it is obtained.

Mr Goettling filled an iron retort with pieces of birch tree bark, and obtained by diffillation a thick, brown, very empyreumatic acid liquor. This liquor he

(u) On this addition, tartar, or acidulated tartrite of potass, is formed, which precipitates, because it is very little soluble in water. The addition of potass dissolves it again.

⁽v) Morveau called this acid fyrupous acid.
(w) Goettling called it ligneous acid.

* Higgins

Acid, p. 2

Pyro lig- allowed to remain at rest for three months, and then se- they are obtained from vegetable substances. We have Veg tab parated from it a quantity of oil which had rifen to the top. By diffilling this liquor again, and then fatura-ting it with potafs, and evaporating to drynefs, he obtained a brown faline mass; which, by being redisfolved in water, and evaporated, yielded greyish white crystals: These crystals were composed of pyro lignous acid and potals. He poured upon them, by little and little, a quantity of fulphuric acid; and by applying a gentle heat, the pyro-lignous acid came over in confide-

+ Crell's Fournal, 1779.

The Dijon academicians obtained this acid from beech wood: by diffilling 55 ounces, they procured 17 ounces of acid; which, when rectified by a fecond distillation, was of the specific gravity 1,02083.

It reddens vegetable colours: when exposed to a ties, combi-strong heat, it takes fire and is destroyed. It unites nations, and very well with alcohol.

Its compounds are called pyro-lignites.

Its affinities, as fixed by Mr Eloy Boursier de Clervaux and Mr de Morveau, are as follows:

Lime, Barytes, Potals, Soda, Magnesia, Ammonia, Oxyd of zinc, - manganese, iron, - lead. - tin. - cobalt, - copper, - nickel, - arfenic. - bismuth, - mercury, -- antimony, - filver, - gold, -- platinum, Alumina, Jargonia †?

1 Vauque-Bin, Ann. de Chim. XXII. 208.

SECT. XXVII. Of Pyro-tartarous Acid.

An acid may also be obtained by distilling tartar; it is called pyro-tartarous acid.

525 It has an empyreumatic taste and odour; reddens the of pyro-tar-tincture of turnfole; but has no effect on that of violets.

Little is known concerning this acid, except that many of its properties are the same with those of the pyro lignous; and Morveau conjectures, that, if properly purified, it would probably be discovered to be the same with it.

The compounds which it forms are called pyro-tartrites.

Its affinities are unknown. Morveau supposes that they are the same with those of the pyro-lignous acid.

526 THE 18 preceding acids are all (except the lactic Vegetable and faccholactic) denominated vegetable acids, because acids,

placed the lactic and faceholactic acids in the fame class; because they bear a strong resemblance to vegetable acids, and because they are evidently composed of the fame ingredients with them.

Vegetable acids are diffinguished from all the acids Destroye described in the beginning of this chapter, by their de-by fire. structibility by fire.

There is no circumstance in chemistry which has at-Convert. tracted greater attention than the possibility of convert-ible into ing the various vegetable acids into each other by means each oth of different processes. To explain what passes during these processes, it would be necessary to know exactly the component parts of every vegetable acid, the manner in which these acids are combined, and the affinities which exist between each of their ingredients. This, however, is very far from being the case at present. Though a vast number of experiments have been made on purpose to throw light on this very point, the difficulties which were to be encountered have been fo great, that no accurate refults have yet been obtained.

It follows from these experiments, that all the vege Enquiry table acids are composed chiefly, at least, of oxygen, hy-to the pr drogen, and carbon; but that the proportions differ in portions every individual acid. We fay chiefly, because it has dients. been suspected from some phenomena, that one or two of these acids contain besides a little azot. Let us take. a view of what is at present known of the composition

of these acids in their order.

1. As to carbonic acid, its composition has been ascertained with tolerable accuracy; it confifts of about 28 parts of carbon and 72 of oxygen.

2. By distilling 7680 grains of acetite of potals, Dr Higgens obtained the following products *:

----3862,994 grains. Acetous Carbonic acid gas, - -1473,564 Carbonated hydrogen gas, - 1047,6018 Refiduum, confifting of carbon, - 78,0000 Oil. - - " 180,0000 Water, 340,0000 Deficiency (x), - -726,9402

This deficiency Dr Higgens found to be owing to a quantity of water and oil which is carried off by the elastic sluids, and afterwards deposited by them. He calculated it, in the prefent case, at 700 grains of water and 26,9402 grains of oil. Now, fince acetite of potals is composed of acetous acid and potals, and fince the whole of the potass remained unaltered, it follows, that the acetous acid was converted into carbonic acid gas, carbonated liydrogen gas, carbon, oil, and water; all of which are composed of oxygen, hydrogen, and carbon.

Now 1473,564 gr. of carbonic acid gas are composed of 1060,966 gr. of oxygen, and 415,598 gr. of carbon.

1047,6018 grains of carbonated hydrogen gas, from a comparison of the experiments of Dr Higgens and Lavoisier, may be supposed to consist of about 714,6008 grains of carbon, and 333,0010 of hydrogen. 200,9402 grains of oil contain 163,4828 grains of

carbon and 43,4574 grains of hydrogen.
1040 grains of water contain 884 grains of oxygen

and 156 grains of hydrogen.

Therefore

Pruffic

Acid.

Therefore 3817,006 grains of acetous acid are composed of 1944,966 — 29,1 = 1915,866 grains of oxygen, 532,4584 grains of hydrogen, and 1368,6816 grains of carbon. Consequently 100 parts of acetous acid are composed of

50,19 oxygen, 13,94 hydrogen, 35,87 carbon.

100,00

These numbers can only be considered as approximations to the truth; for the object of Dr Higgins was not to afcertain the proportions of the ingredients which compole acetous acid; and therefore his experiments were not conducted with that rigid accuracy which would have been necessary for that purpose.

It is extremely probable, that during the acetous fermentation, or the conversion of alcohol into acetous 1 mfladt, acid, a quantity of water is formed *; and it is certain that oxygen is absorbed. It follows from this, that acetous acid contains more carbon and less hydrogen than alcohol. Now we have reason, from Lavoisier's experiments, to believe, that alcohol is formed of

51,72 oxygen, 18,40 hydrogen, 29,88 carbon.

Lavoisier supposes that this acid contains also azot. 3. Acetic acid is supposed to consist of the same hase with acetous acid, combined with a larger proportion of oxygen; we would rather fay, that it is ace-

tous acid combined with oxygen.

4. When oxalic acid is distilled with fix times its weight of fulphuric acid, the products are acetous acid, fulphurous acid, carbonic acid gas, and fulphuric acid remains in the retort †. Hence it follows, that oxalic acid contains more carbon than acetous acid; but that 1785 it is composed of the same ingredients. It has been supposed, that oxalic acid is composed of sugar and oxygen. Now sugar, according to Lavoisier, is composed of

Hydrogen, Oxygen, Carbon,

These proportions are rather unfavourable to that notion; at least if any dependence can be put in the composition of acetous acid as deduced from the expe-

riments of Dr Higgins.

5. Hermstadt dissolved four ounces of tartarous acid in 16 ounces of water, and kept the folution in a vessel covered with paper in a warm place. In three months the taste of the folution was changed, and the air in the upper part of the veffel was found to be carbonic acid. In fix months the folution was converted into acetous acid. It follows from this experiment, that tartarous acid contains more carbon than acetous acid, and that their ingredients are the same. If any doubts should remain, the following experiment is fufficient to remove them. Westrum mixed strong sulphuric acid with tartarous acid, and added manganese; acetous acid was produced, and a great quantity of carbonic acid gas was difengaged. When nitric acid is diffilled off tartarous acid, it is converted into oxalic acid, as Scheele first proved. Hence it has been supposed by some, that oxalic acid differs from tartarous merely in containing more oxygen; but this is very far indeed from be-

ing proved. According to Hassenfratz, tartarous acid contains a confiderable quantity of azot.

6. When citrat of lime is allowed to remain in a bottle flightly corked along with a little alcohol, the citric acid is gradually converted into acetous acid ‡. ‡ Stabl. Westrum converted it into oxalic acid by means of ni-

tric acid.

7. Malic acid was converted into oxalic by means of nitric acid by Scheele. It has been supposed to contain more oxygen than oxalic acid. Some of it is always formed during the common process of converting fugar into oxalic acid. Were we to judge from an experiment, which, however, was not performed with fufficient accuracy, we would conclude that the base of malic acid is gum; for by distilling two parts of weak nitric acid off one part of gum in a very small heat, we obtained a quantity of acid more in weight than the gum, which exhibited several of the diftinguishing properties of malic acid. It was exceedingly light, white, and fpongy, and attracted water very quickly from the atmosphere, and could not afterwards be brought by evaporation to its former state.

8. Scheele converted lactic acid into acetous by mere exposure to the atmosphere, and found that a quantity of carbonic acid was difengaged. Hence this acid is merely the acetous with a smaller proportion of

9. The gallic acid, we have feen, contains more car-

bon than any of the others.

10. Nothing is known concerning the composition of the benzoic and fuccinic acids. Hermstadt says he converted benzoic acid to oxalia by means of nitric acid: but Morveau did not observe that any change was pro-

11. The base of camphoric is probably camphor.

Though these eighteen are the only acids which have hitherto been examined with attention, it cannot be doubted that the number of vegetable acids, either existing naturally, or at least capable of being formed by art, is confiderably greater. Morveau has lately ascertained, that the red colours of flowers are owing to acids: This had already been conjectured by Linnæus.

SECT. XXVIII. Of Pruffic Acid.

ABOUT the beginning of the present century, Dies- Discovery bach, a chemist of Berlin, wishing to precipitate a solu-of Prussian tion of cochineal mixed with a little alum and fulphat blue. of iron, borrowed from Dippel some potals, from which that chemist had distilled several times his animal oil. On pouring in the potafs, Diesbach was surprised to see, instead of the red precipitate which he had expected, a beautiful blue powder falling to the bottom of the vessel. By reflecting on the materials which he had employed, he easily discovered the method of procuring the blue powder at pleasure *. This powder was called Prussian * Stabl's blue, from the place where it was discovered. It was 300 Expeannounced in the Berlin Memoirs for 1710; but the riments. process was concealed, because it had become a lucrative article of commerce. A method of preparing it, Method of however, was published by Woodward in the Philoso-preparing phical Transactions for 1724, which he said he had got it from one of his friends in Germany This method was as follows: Detonate together 4 ounces of nitre and as much tartar, in order to procure an extemporaneous alkali; then add 4 ounces of dried bullock's blood, mix

the ingredients well together, and put them into a crucible covered with a lid, in which there is a fmall hole; calcine with a moderate fire till the blood emits no more fmoke or flame capable of blackening any white body exposed to it: increase the fire towards the end, so that the whole matter contained in the crucible shall be moderately but fenfably red. In this state throw it into two pints of water, and boil it for half an hour. Decant off this water, and continue to pour on more till it come off insipid. Add all these liquids together, and boil them down to two pints. Dissolve two ounces of fulphat of iron and eight ounces of alum in two pints of boiling water; mix this with the former liquor while both are hot. An effervescence takes place, and a powder is precipitated of a green colour mixed with blue. Separate this precipitate by filtration, and pour muriatic acid upon it till it becomes of a beautiful blue; then wash it with water and dry it.

Different explanations were given of the nature of this precipitate by different chemists. All of them acknowledged that it contained iron, but to account for the colour was the difficult point. Brown, and Geoffroy, and Neumann, discovered in succession, that a great many other animal substances besides blood communicated to alkalis the property of forming Pruffian blue. Macquer undertook an examination of this fubstance, and published the result of his experiments in the Me-

moirs of the French Academy for 1752.

Macquer.

He observed, that when alkali is added to a solufition difection of iron in any acid, the iron is precipitated of a yellow colour, and soluble in acids; but if iron be precipitated from an acid by an alkali prepared as above described, by calcination with blood (which has been called a Prussian alkali), it is of a green colour. diffolve only a part of this precipitate, and leave behind an infoluble powder which is of an intense blue colour. The green precipitate therefore is composed of two different fubstances, one of which is Prussian blue; the other, as he afcertained by experiment, is the brown or yellow oxyd of iron; and the green colour is owing to the mixture of the blue and yellow fubftances. heat is applied to the infoluble precipitate, its blue colour is destroyed, and it becomes exactly similar to common oxyd of iron. It is composed therefore of iron and fome other fubstance, which heat has the property of driving off. If this infoluble precipitate be boiled with a very pure alkali, it loses its blue colour also, and at the fame time the alkali acquires the property of precipitating of a blue colour folutions of iron in acids, or it has become precifely the fame with the Prussian alkali. Pruffian blue, therefore, is composed of iron and something which a pure alkali can separate from it, fomething which has a greater affinity for alkali than for iron. By boiling a quantity of alkali with Pruffian blue, it may be completely faturated with this fomething, which we shall call colouring matter, and then it has lost all its alkaline properties. No acid can feparate this colouring matter from iron after it is once united with it. When iron diffolved in an acid is mixed with an alkali faturated with the colouring matter, a double decompofition takes place, the acid unites with the alkali, and the colouring matter with the iron, and forms Pruffian blue. The reason that, in the common method of preparing Pruffian blue, a quantity of yellow oxyd is precipitated, is, that there is not a fufficient quantity of colouring matter (for the alkali is never faturated with it) to saturate all the iron displaced by the alkali; a part of it therefore is mixed with Prussian blue. Muriatic acid diffolves this oxyd, carries it off, and leaves the blue in a flate of purity. Such were the conclusions which Macquer drew from his experiments; experiments which not only discovered the composition of Prussian blue, but threw a ray of light on the nature of affinities, which has contributed much towards the advancement of that important branch of chemittry.

The nature of the colouring matter, however, was flill unknown. Macquer himself supposed, that it was pure phlogiston; but the opinion was untenable. He had shewn that it possessed the property of forming neutral falts, and therefore Bergman and Morveau inspected

that it was an acid.

Scheele undertook the task of examining its nature, and published the result of his experiments in the Stockholm Transactions for 1782.

He observed, that the Prussian alkali, after being exposed for some time to the air, lost the property of forming Prussian blue; the colouring matter must therefore

have lest it.

He put a small quantity of it into a large glass globe, Decom corked it up, and kept it some time; but no changesed by was produced either in the air or the Pruffian alkali. Scheele, Something must therefore displace the colouring matter when the alkali is exposed to the open air, which is not present in a glafs vessel. Was it carbonic acid gas? To afcertain this, he put a quantity of Pruffian alkali into a glass globe filled with that gas, and in 24 hours the alkali was incapable of producing Prussian blue. It is therefore carbonic acid gas which difplaces the colouring matter. He repeated this experiment with this difference, that he hung in the globe a bit of paper which had been previously dipped into a folution of sulphat of iron, and on which he had let fall two drops of an alkaline lixivium, in order to precipitate the iron. This paper was taken out in two hours, and became covered with a fine blue on adding a little muriatic acid. Carbonic acid, then, has the property of feparating the colouring matter from alkali without decomposing it.

He found also that other acids produced the same ef- The color fect. The colouring matter then may be obtained per ing matter haps in a separate state. He accordingly made a num-separated ber of attempts to procure it, and at last discovered the following process: He boiled together for some minutes two ounces of Prussian blue in powder, one ounce of the red oxyd of mercury, and fix ounces of water; then passed the whole through a filter, and washed the residuum with two ounces of boiling water. The oxyd of mercury has a greater affinity for the colouring matter than the oxyd of iron; it therefore unites with it, and forms with it a falt foluble in water. The iron remains behind upon the filter, and the liquid is a folution of the colouring matter combined with mercury. He poured this folution upon half an ounce of pure iron-filings, and added at the fame time three grains of sulphuric acid. The iron separates the oxygen from the mercury, in order to combine with the fulphuric acid; the mercury is precipitated in its metallic state, and leaves behind it a quantity of sulphat of iron and of colouring matter diffolved in water, but not combined, as the colouring * Bertoolle, matter is unable to feparate the iron from the acid *.

He then distilled in a gentle heat; the colouring mat- Chimie, is

ter came over by the time that one fourth of the liquor had passed into the receiver. It was mixed, however, with a small quantity of sulphuric acid; from which he separated it by distilling a second time over a quantity of carbonat of lime. The sulphuric acid combines with the lime and remains behind, which the colouring matter cannot do, because carbonic acid has a stronger assisting for lime than it has. Thus he obtained the colouring matter in a state of purity.

It remained now to discover its component parts. He arts. formed a very pure Pruffian blue, which he distilled, and increased the fire till the vessel became red. The small quantity of water which he had put into the receiver contained a portion of the blue colouring matter and of ammonia; and the air of the receiver confifted of azot, carbonic acid gas, and the colouring matter. He concluded from this experiment, that the colouring matter was composed of ammonia and carbon. He mixed together equal quantities of pounded chargoal and potals, put the mixture into a crucible, and kept it red hot for a quarter of an hour: he then added a quantity of fal ammoniac in small pieces, which he pushed to the bottom of the melted mixture, kept it in the fire for two minutes till it had ceased to give out vapours of ammoria, and then threw it into a quantity of water. The solution possessed all the properties of the Prussian alkali. Thus Mr Scheele succeeded in forming the colouring matter; and it was confidered as proved that it was composed of ammonia and carbon.

But after the publication of Scheele's experiments, it was discovered that ammonia itself is composed of azot and hydrogen. It became therefore a question, whether ammonia entered into the composition of this substance, or merely its ingredients? whether it was composed of ammonia and carbon, or of azot, hydrogen, and carbon combined in a different manner? This point has been decided by the following experiments. Mr Clouet made a quantity of ammoniacal gas pass thro' a red hot porcelain tube filled with charcoal, and by this process formed a quantity of the colouring matter *. Here the temperature was so high that the ammonia must have been decomposed: and the colouring matter cannot be formed by combining ammonia and charcoal except at a temperature equally high. There is reason therefore to suppose that the ammonia is decomposed. When oxy-muriatic acid is mixed with the colouring matter, it communicates to it a quantity of oxygen, and causes it in consequence to assume very different proper-When a fixed alkali or lime is added to it in this state, it is immediately decomposed, and converted into ammonia and carbonic acid gas. The colouring matter in this flate contains all the ingredients necessary to form these two substances, namely, azot, hydrogen, carbon, oxygen; but in order to induce the ingredients to form these two compounds, the affistance of an alkali or lime to combine with the carbonic acid is necessary; just as fulphur combines more easily with oxygen when united tholles, with an alkali or with iron than when feparate *.

SUPPL. Vol. I. Part I.

The colouring matter, then, which we shall henceforth call the *Prussic acid*, is composed of azot, hydrogen, and carbon; but the proportions of these ingredients have not yet been determined. It is considered as an acid, though the presence of oxyen has not been proved, because it has the property of forming neutral salts with the same bases as other acids.

The Pruffic acid is exceedingly volatile, and evident-Properties ly capable of existing in a gaseous state. It has a pecu of Pruffic liar odour, not disagreeable, and which has been compared to the slowers of the peach. It has a sweetish and somewhat hot taste, and excites cough †.

It has no affinity for alumina nor for alcohol ‡.
This fubfiance differs exceedingly in its action from

all other acids.

It is capable of combining, like them, with earths, Its action alkalies, and metallic oxyds, and of forming compounds on other which have been denominated Prusiats. But it enters much more readily into triple compounds with alkalies or earths, and metallic oxyds, than into combinations with carths or alkalies feparately; and though its affinity appears to be greater for alkalies and earths than for metallic oxyds, yet when in a free or gaseous state it does not enter into combinations with earths or alkalies without difficulty, and it is separated from them much more easily than from metallic oxyds. Mere exposure to the light of the sun, or to a heat of 110°, is sufficient for that purpose.

Its affinities are supposed to be as follows:

Its affini-Potass, Soda, Ammonia, Lime, Barytes, Magnesia, Oxyd of zinc, - manganele, - cobalt, - nickel, - lead, -- tin, - copper, - bifmuth, antimony, - arfenic, filver, - mercury, - gold, - platinum (Y).

SECT. XXIX. Of Formic Acid.

In the 15th century feveral botanists observed with Discovery astonishment, that the flower of succery, when thrown formic into an ant-hill, became as red as blood: But it was acid.

Mr S. Fisher who first discovered that ants possessed a peculiar acid, which he obtained by distilling these animals. His experiments were published in the Philosophian.

⁽v) We suspect that this is not the real order of the assinities of this acid; the metallic oxyds ought probably to be placed before the alkalies and earths, and the metallic Prussias ought to occupy the place which is at prefent silled by the metallic oxyds. The reasons for this conjecture will appear afterwards. See Part III. chap. ii. sect. 23. of this article.

Formic

cal Transactions for 1670. Though Hoffman afterwards repeated his process, little was known concerning the nature of this acid till Margraf undertook its examination, and published his experiments in the Berlin Memoirs for 1749.

The species of ants from which the formic acid is obtained is the formica rufa, which refide most commonly in woods, or at least in elevated and dry places. They have been found to contain the greatest quantity of acid in the months of June and July. If at that feason one of these animals be pressed upon paper tinged with turnfole, it changes the colour of it to a most lively red: they even fometimes stain it merely by crawling over it.

Methods of obtaining it.

There are two methods of obtaining the formic acid, distillation and lixiviation.

When the first method is to be employed, the ants are to be washed clean, dried with a gentle heat, put into a retort, and distilled with a moderate heat, gradually increased till all the acid has come over. It is mixed with an empyreumatic oil, from which it is separated by paffing it through a strainer previously moistened with water. By this process Messrs Ardvisson and Othern obtained from a pound of ants 71 ounces of acid, the specific gravity of which, at the temperature of 60° # Differt, on was 1,0075 *. Morveau obtained from 49 ounces of

the Acid of ants 23 ounces of pretty strong acid +. Margraf added Ants, 1777, a quantity of water, but it is evident that this serves ger's New merely to weaken the acid.

Magazine When the orl

When the other method is preferred, the ants are to be washed in cold water, put upon a clean linen cloth, and boiling water poured on them repeatedly till it can extract no more acid. The linen is then to be squeezed, and the feveral liquors mixed and filtrated. This mcthod was first used by Ardvisson and Oehrn: they obtained from a pound of ants an acid liquor which had more specific gravity than common vinegar. It is to be purified from the oil which adheres to it by repeated distillations. After four distillations the empyreumatic oil still manifests its presence by its smell, but this smell vanishes if the acid be exposed for some time to the air; a quantity of effential oil, however, still remains, which cannot be separated. The specific gravity of the acid † Ardvisson thus rectified is 1,0011 ‡.

+ Encycl.

Method. i.

Hermstadt employed a third method. He expressed the juice of dry ants, and by this means obtained from 2 lbs. of these animals 21 oz. 2 dr. of juice, which on distillation yielded a clear pure acid, equal in strength to

very concentrated vinegar *.

This acid feems to be capable of affuming a gaseous form; at least Hermstadt observed, that when he put Its properfome of it into a bottle with a glass stopper, the stopper was frequently raifed by an elastic sluid making its escape, and that after some days it had lost its smell +. When this acid is boiled with nitric acid, a gas is extricated, which renders lime water turbid, and has a

† Ardvisson, very pungent odour †.

This acid has a strong but not unpleasant smell, a caustic taste, and when much diluted a pleasant acidity. When most concentrated, its specific gravity is 1,0453‡.

One part of this acid, mixed with 75 parts of water, gives a faint red to syrup of violets; mixed with 430

It unites readily with the other acids. When boiled with fulphuric acid, it becomes black. White acrid vapours rife when the mixture becomes hot; and when it boils, a gas rifes which unites with difficulty to water and lime-water; the formic acid is again obtained, but § Ibid. its quantity is dinmished v.

Nitric acid decomposes it altogether, and is itself Muriatic acid does not alconverted into nitrous acid. ter it. Oxy-muriatic acts like nitric acid *.

Its compounds are called formiats.

Its affinities are the same with those given above for pounds, the Pruffic acid.

SECT. XXX. Of Sebacic Acid.

CHEMISTS had long suspected that an acid could be Discove obtained from tallow, on account of the acrid nature of of febac the fumes which it emitted at a high temperature; but acid, it was M. Grutzmacher who first demonstrated this acid in a differtation De Offium Medulla, published in 1748 1. Leonh. M. Rhodes mentioned it in 1753, and Segner published a differtation on it in 1754, and Crell examined its properties very fully in two differtations published in the Phil. Trans. for 1780 and 1782. It was called at first acid of fat, and afterwards febacic acid.

It may be procured by heating together a mixture of fuet and lime. Sebat of lime is formed, which may be purified by folution in water. It is then to be put into a retort, and fulphuric acid poured on it. Sebacic

acid passes over on the application of heat.

Sebacic acid has an acid, sharp, bitterish taste, and a sts proper very pungent smell. It reddens tincture of litmus. Heat causes it to assume a yellow colour.

It oxydates filver, mercury, copper, iron, lead, tin, zinc, antimony, manganese.

It does not act upon bismuth, cobalt, nickel. When mixed with nitric acid it dissolves gold.

Its compounds are called febats.

545 Com-Ite affinities, according to Morveau, are as follows: pounds, Barytes, and affi-Potafs, Soda, Lime, Magnesia, Ammonia, Alumina, Jargonia†, Oxyd of zinc, Ann. de Chim. XX - manganese, 208. - iron, - lead, - tin, --- cobalt, - copper, - nickel, - arfenic, -- bismuth, - mercury, - antimony, -- filver.

SECT. XXX. Of Bombyc Acid.

MR Boissier De Sauvages observed, that the juice Discover, parts of water, it reddens paper coloured with turnfole; of the filkworm, in the disease called in France musca-of bomb mixed with 1300 parts of water, it produces no effect dine, was acid; and Chaussier remarked, that the filk acid. # Morveau, on the infusion of turnsole #. It mixes readily with al- worm, after being converted into a butterfly, gives out

By means of a pair of scissars he collected some which reddened blue paper, united with alkalies with effervescence, and even attacked the scissars. He afterwards collected it by infufing the chryfalids in alcohol, which diffolved the acid, but left the impurities un-

This acid has never been examined with attention; fo that almost all its properties are unknown.

SECT. XXXI. Of Zoonic Acid.

MR BERTHOLLET has obtained a peculiar acid by dii od of stilling vegetable and animal substances, to which he has given the name of the zoonic acid+. He procured it by diffilling the gluten of wheat, the yest of beer, bones, and xxvi. woollen rags; and concludes, therefore, that it may be produced by the distillation of all animal substances.

To obtain this acid pure, he mixed lime with the distilled liquid, after having separated the oil, which it always contains (for the product of the distillation of animal substances is chiefly oil and carbonat of ammonia). He boiled this mixture till the carbonat of ammonia was exhaled: he then filtered it, added a little more lime, and boiled it again till the smell of the ammonia had gone off entirely. The liquor, which now contained only zoonat of lime, he filtered again, and then added a little water impregnated with carbonic acid, in order to precipitate any lime which might happen to be diffolved in the liquid without being combined with the zoonic acid.

After concentrating the zoonat of lime, he mixed it with phosphoric acid, and distilled it in a retort. At a heat nearly equal to that of boiling water, the zoonic acid passes over in a state of purity.

The zoonic acid has an odour like that of meat when frying, and it is actually formed during that process. It has an austere taste.

It gives a red colour to paper tinged with turnfole. With alkalies and earths it produces falts, which do not appear capable of crystallizing.

It forms a white precipitate in the folutions of ace-

tite of lead and nitrat of mercury.

Part of the zoonic acid feems to be destroyed by the action of heat during the diffillation of the zoonat of lime with phosphoric acid: for the liquor, which is in ebulition, becomes brown, and grows black at the end of the operation; hence Mr Berthollet concludes that the zoonic acid contains carbon. The zoonat of filver, when kept, becomes gradually brown; hence he concludes that the acid contains hydrogen. These conclutions he draws from a very ingenious theory of his, which has been already described in the article BLEACH-Berthollet, ING in this Supplement *.

The five preceding acids have obtained the name of im. xxvi. animal acids, because they are all obtained from the animal kingdom. It can fcarcely be doubted that a more accurate examination of animal fubstances will add con-

fiderably to the number of these acids.

in. de

ids.

SECT. XXXII. Of Arfenic Acid.

ARSENIC acid, which was first discovered by Scheele, may be produced by fimply mixing the white oxyd of

a liquor which turns vegetable blues to a red. He found, arfenic with oxy-muriatic acid, and applying a heat further that during the time that the animal was forming its ficient to sublime the muriatic acid. The theory of this operation is evident: the white oxyd has a greater.

By the substitute of affinity for oxygen than muriatic acid has; of course Method of it combines with it, and is thus converted into arfenic obtaining acid, and the muriatic acid is eafily fublimed by apply-arfetic acid. ing heat.

Landriani has informed us, that this acid may be alfo formed by fubliming feveral times successively the white oxyd of arfenic, and taking care every time to renew the air. This process is equally simple; the oxyd combines at a high temperature with the oxygen of the

atmosphere. This acid is exceedingly fixed. When exposed to its properthe air it attracts humidity, and at last becomes li-ties. quid. At the temperature of 60° it dissolves in twothirds of its weight of water. Its folution may be evaporated to dryness, and even converted into a glass, which attracts moisture from the air, and acts powerfully on the crucible.

It is poisonous as well as the white oxyd of arfe* Scheele-

When exposed to a red heat, it is partly decomposed and converted into white oxyd of arfenic +.

It does not act upon gold, platinum, filver, mer-

It oxydates copper, iron, lead, tin, zinc, bismuth, antimony, cobalt, nickel, manganese, and arsenic, and in a very strong heat mercury and filver.

According to Berthollet's experiments, arfenic acid is composed of eight parts of white oxyd of arsenic and one part of oxygen.

Its compounds are called arseniats. Its affinities are as follows:

Lime, Barytes, Magnefia, Potass, Soda, Ammonia, Oxyd of zinc, - manganele,

_ - iron, ---- lead, --- tin, - cobalt, - copper, - ___ nickel,

--- bifmuth, - mercury, - antimony,

- filver, gold, - platinum,

SECT. XXXIV. Of Molybdic Acid.

Properties CONCRETE molybdic acid, first discovered by Scheele, is white, and has an acid but metallic taste. Its specific gravity is 3,75 *. It is not altered in the air. When * Bergman. heated in a crucible till it is beginning to melt, it experiences no alteration. It remains fixed even in a great fire as long as the crucible is covered; but the moment it is uncovered the acid rifes unaltered in a white smoke. It dissolves in 570 parts of water. The solution reddens turnfole ; nitric acid does not affect it, but sulphuric and muriatic acids diffolve it by the affiltance of

It may be prepared by treating the ore of molybdenum with nitric acid, and washing the acid when form-

When combined with potals, it forms a colourless falt.

Mixed with filings of tin and muriatic acid, it immediately becomes blue, and precipitates flakes of the same colour, which disappear after some time, if an excess of muriatic acid has been added, and the liquor affumes a brownish colour.

With the foliation of nitrat of lead it forms a white precipitate, foluble in nitric acid.

When mixed with a little alcohol and nitric acid, it does not change its colour.

With a folution of nitrat of mercury, or of nitrat of filver, it gives a white flaky precipitate.

With the nitrat of copper it forms a greenish precipitate

With folutions of fulphat of zinc, muriat of bifmuth, muriat of antimony, nitrat of nickel, muriats of gold and platinum, it produces white precipitates when these folutions do not contain an excess of acid.

When melted with borax, it gives it a bluish co-

Paper dipt in this acid becomes in the fun of a beau-* Vauquelin, tiful blue colour *.

Philosophical Mugazine, i. 282.

Sulphur is capable of partly decomposing it by heat. Its compounds are called molybdats.

Its affinities are unknown.

SECT. XXXV. Of Chromic Acid.

In the year 1770, Mr Pallas discovered, in the gold mine of Beresof, near Ekaterimbourg in Siberia, a mi- Analysi neral of a red colour, with a fhade of yellow, cryftallized the red in small acute angled quadrangular prisms, sometimes of Siber fmooth, fometimes longitudinally streaked, and often hollow. Mr Macquart, professor of medicine at Paris, who in 1783 had been fent to the north by the French government in order to collect mineralogical information, brought with him a quantity of this mineral, which has been distinguished by the name of red lead ore of Siberia, and in 1789 analysed four ounces of it along with Mr Vauquelin. They found it to contain,

Lead Oxygen 37 8 Iron 240 Alumina 2 ICOT

and a little filver *.

Mr Bindheim of Moscow analysed it soon after, and Chim.i. * Ann. de found it to contain,

Lead Molybdic acid 11,66 Nickel 5,66 Oxyd of iron Air and water 5 4,5

and a little copper and cobalt +. Vauquelin examined it again in 1797, and found Beeb iv. that all the former analyses were inaccurate.

A hundred parts of this mineral, reduced to a fine powder, were mixed with 300 parts of the faturated carbonat of potass, and about 4000 parts of water; and this mixture was expoled for an hour to a boiling heat. He observed, 1st, that when these matters began to act upon each other there was produced a firong effervelcence, which continued a long time; 2d, that the orange colour of the lead became a brick red; 3d, that at a certain period the whole matter feemed to diffolve; 4th, that in proportion as the effervefcence advanced the matter reappeared under the form of a granulated powder, of a dirty yellow colour; 5th, that the liquor affumed a beautiful golden yellow colour. When the effervescence had entirely subsided, and appeared to have no longer any action on the fubitances, the liquor was filtered, and the metallic dust collected on the paper. After being washed and dried, it weighed no more than 78 parts: the potals, therefore, had taken from it 22 parts.

He poured upon the 78 parts just mentioned fome of the nitric acid, diluted in 12 parts of water, which produced a brilk effervescence. The greater part of the matter was diffolved: the liquor affumed no colour, and there remained only a finall quantity of powder of an orange-yellow colour. The liquor of the refiduum was separated by the help of a syphon, the matter washed several times, and the washings united with the first liquor. This refiduum, dried, weighed no more than 14 parts: from which it follows, that the nitric acid had dissolved 64.

He again mixed these 14 parts with 42 parts of the carbonat of potass and the necessary quantity of water,

comic and then treated them as before, and the phenomena were the same. The liquor, after being filtered, was united to the former; and the refiduum, washed and dried, weighed no more than two parts, which were still red lead, and therefore thrown away.

The two nitric folutions, united and evaporated, produced 92 parts of nitrat of lead, crysfallized in octahedra, perfectly white and transparent. These 92 parts of nitrat of lead, disfolved in water, were precipitated by a folution of the fulphat of foda. This produced 81 parts of the fulphat of lead, which were equivalent to 56,68 of metallic lead.

The alkaline liquors were found to contain a falt composed of potal's combined with a peculiar acid, which Mr Vauquelin afterwards called chromic acid.

These liquors, subjected to evaporation until a saline pellicle was formed on their furface, produced, on cooling, yellow crystals; among which there was carbonat or potass, not decomposed. These crystals dissolved in water, and the folution united with the mother water, the whole was mixed with weak nitric acid until the carbonat of potafs was faturated. The liquor then had a very dark orange red colour. Being united with a folution of the muriat of tin, newly made, it first affumed a brown colour, which afterwards became greenish. Mixed with a folution of the nitrat of lead, it immediately produced the red lead. Laftly, evaporated fpontaneously, it produced ruby-red crystals, mixed with crystals of the nitrat of potals. Ninety eight parts of this mineral, decomposed as above mentioned, having produced 81 parts of the sulphat of lead, 100 parts would have given 82,65, which are equivalent to 57,1 of metallic lead. " But admitting, as experiment proves (lays Mr Vauquelin). that 100 parts of lead absorb, in combining with acids, 12 parts of oxygen, the 57,1 of metallic lead ought to contain in the red lead 6,86 of this principle, and we ought to have for the mineralizing acid 36,4.

Chromic acid crystallizes in the form of elongated

prisms of a ruby colour.

When mixed with filings of tin and the muriatic acid, it becomes at first yellowish brown, and afterwards

assumes a beautiful green colour.

When mixed with a little alcohol and nitric acid, it immediately affumes a bluish green colour, which preferves the same shade even after deliccation. alone gives it the fame colour.

With a folution of nitrat of mercury, it gives a pre-

cipitate of a dark cinnabar colour.

With a folution of nitrat of filver, it gives a precipitate, which, the moment it is formed, appears of a beautiful carmine colour, but becomes purple by exposure to the light. This combination, exposed to the heat of the blow-pipe, melts before the charcoal is inflamed. It assumes a blackish and metallic appearance. If it be then pulverifed, the powder is still purple; but after the blue flame of the lamp is brought in contact with this matter, it affumes a green colour, and the filver appears in globules diffeminated throughout its fubstance.

With nitrat of copper, it gives a chesnut red precipi-

With the folutions of fulphat of zinc, muriat of bifmuth, mnriat of antimony, nitrat of nickel and muriat of platinum, it produces yellowish precipitates when these solutions do not contain excess of acid. With Chromic muriat of gold, it produces a greenish precipitate.

When melted with borax or glass, it communicates to them a beautiful emerald green colour.

Paper impregnated with chromic acid affumes in the

light a greenish colour.

When mixed with muriatic acid, the mixture was capable of diffolving gold like aqua regia; when this mixture of the two acids is distilled, oxy-muriatic acid is difengaged, and the liquor affumes a very beautiful green colour.

Sulphuric acid, while cold, produces no effect upon it; but when warmed, it makes it affame a bluish green colour, probably by favouring the difengagement of oxygen.

When this acid is heated along with charcoal, it is reduced to the metal called chromum. It is there'ore composed of this metal and oxygen. From Vauquelin's experiments, it appears to contain one part of chromum and two parts of oxygen.

Such are the properties of this acid, as far as they have hitherto been discovered. Vauguelin is the only chemit who has examined it; and from his memoir the * Ann. de

above account has been taken *.

The four last described acids are called metallic acids, Magazine, because they are composed of metals and oxygen.

It is believed, that most of the metals, we would ra-361 ther fay of the metallic oxyds, are capable of being Metallic converted into acids by being combined with oxygen, acids. It is certain that this is the case with platinum; and Hermstadt, by distilling nitric acid off tin, converted it into a white mass, soluble in three parts of water, which has been called flannic acid +. Several more of † Ann. de the metallic oxyds act the part of acids: But no com. 162. plete fet of experiments on this important subject has yet appeared.

CHAP. VI. Of AFFINITY.

THE meaning of the word affin. has been already importance explained; and it must appear evident, from the use of affinity. which has been made of it in this article, that the confideration of the nature of affinity is the most important part of chemistry. While its laws are unknown, chemistry is not a science, but a wilderness of facts without heauty or regularity: every thing is equally perplexing and incomprehensible. The chemist, instead of being able to trace the operations of Nature, is loft in an endless maze of uncertainty, without a guide to conduct him, or a ray of light to illuminate his steps. It is the knowledge of affinity which dispels the darkness, removes the confusion, shews us the order which fubfifts in all the phenomena of nature, points out their dependence on one another, and enables us to direct them as we think proper, to make them subservent to the improvement of the arts, and thus to render them the ministers of our comforts and enjoyments.

1. When two bodies are united together by affinity, It unites how small a portion soever of the compound we exa-ticle to parmine, we shall always find it to contain both of the in-ticle. gredients. From this it is evident, that affinity com-

bines bodies, particle with particle.

By particles we do not mean what philosophers have called atoms, or the smallest parts into which it is posfible to divide matter; but the finallest parts which

Chim. XXV.

Philofophical

Affinity. make an integrant of any substance. Water, for instance, confists of oxygen and hydrogen; but when we speak of a particle of water, we do not mean the oxygen or the hydrogen separately, but the smallest posfible quantity of these combined in such a manner as to form water. It is the integrant particles of bodies which are united by affinity. Thus fulphuric acid is compofed of fulphur and oxygen combined together; and ammonia, of hydrogen and azot combined in the same manner. Now when fulphuric acid and ammonia combine, it is not their elements, fulohur, oxygen azot, and hydrogen, which unite together, particle with particle, but the particles of the acid and the alkali as integrants. This is evident; because if these substances be separated from each other by means of a stronger affinity, they are found precifely in the same state as before they entered into combination. - When the substances which combine are fimple, the ultimate and integrant particles are the same: But we are not certain that any of the bodies with which we are acquainted is fimple, in the strict and proper sense of the word.

Opinions er chemists pinout affinity.

2. What is this affinity which unites bodies together? of the old- The older chemists thought that all solvents, or substances capable of dissolving others, were composed of particles which had the form of wedges or hooks; that folution confifted in the infinuation of these wedges or hooks between the particles of the bodies to be disfolved; and that chemical combination was merely the linking of the different particles together by means of holes in one fet of particles, into which the hooks or the wedges of the other fet were thrust. Such explanations, absurd as they may appear, were fashionable among chemical philosophers till the days of Sir Isaac Newton, who first ascribed the chemical union of bodies to an attraction between the particles themselves. This explanation, after a violent struggle on the part of the chemists, has been at last unanimously adopted.

363 It is an at-

Affinity, then, is an attraction between the particles traction be- of different bodies, by which they are drawn towards particles of one another, and kept united. This we take for granted, and consider as a fall, without pretending to explain how they come to be possessed of this power, or how they exert it; both of which are evidently beyond the reach of the human understanding.

But though we cannot discover the manner in which affinity acts, we can fee, at least, that it follows certain laws, and that they are invariable; for fimilar phenomena always occur when the circumstances are the same. Now what are the laws which affinity follows? There is a species of attraction which matter possesses, called gravitation, the laws of which were investigated by Sir Isaac Newton. Is affinity the same with gravitation, or does it follow different laws?

Upon a flight view of these two attractions, their phenomena appear very different. Gravitation acts at very great distances; affinity not until the bodies are mixed together: Gravitation acts on the whole mass; affinity only on the particles: Bodies gravitate to one another directly as their masses, and inversely as the squares of their distances. But how can affinity follow these laws, when it does not act till the bodies are ap-

parently in contact? or supposing that it does act, how Affini can they account for the phenomena of affinity? If barytes be prefented to a compound of fulphuric acid and potals, the acid immediately leaves the alkali and combines with the earth: But had gravitation been the only power acting, ought not the barytes to have united with the fulphat of potafs without producing any decomposition?

These striking differences have convinced many philosophers, as they feem to have done Newton himself, that gravitation and affinity are different species of attraction. Let us not, however, embrace this conclufion vaguely, or without affixing a precise meaning to

our words.

Gravitation and chemical affinity are faid to be diffe- No jost rent species of attraction. But what is attraction? It is proof the merely a general fact, or that tendency which is observed it is different in the control of the among all the portions of matter towards each other, rent. but which exhibits very different appearances under different circumstances. The tendency of matter towards matter at fensible distances is called gravitation, and its laws have been completely investigated; but neither that tendency, nor these laws, have been, or can be, shewn to be effential to the existence of matter. Chemical affinity is the tendency of particles towards each other at infenfible distances, or when these particles are mixed together; and this tendency appears to be regulated by laws different from those of gravitation. Like gravitation, it is merely an observed fact; and however different these facts may appear to be, they are probably both brought about by the same forces. It is indeed true, that gravitation is directly as the maffes of matter, and inversely as the squares of the distances of these masses; while the attraction, which is called chemical affinity, seems to observe very different rules. But we have shewn elsewhere (see Orrics, nº 62-68, Encycl.; and Boscovich in this Suppl.), that the same forces repel at one distance and attract at another; and that they may produce all the various phenomena of chemical affinity.

The difficulties to be accounted for in chemical affinities are their intensity, their different degrees of strength, and their being elective, or, which is the same thing, the capacity which one body has of displacing

another.

How come affinities, it may be asked, to differ in intenfity? Perhaps we might with propriety refer this querift to the study of Boscovich's curve; but as our modern chemists are not generally versant in such studies, we beg leave to observe, in this place, that we have no proof whatever of absolute contact between bodies. On the contrary, it is highly probable, we had almost said demonstrable, that particles are in every instance at fome distance from one another. For, on the supposition that two bodies were in actual contact, their attraction for each other would not only be as great as poffible, but as great as the attraction of any other body for either of them could possibly be: Consequently, it necessarily follows, that, fince bodies chemically combined can be separated, they are not in actual contact (A); but if they are not in contact, their distance from one

another

564 Whether the fame with gra-Vitation.

> Plate XVIII.

(A) Perhaps the following demonstration, which we borrow from the ingenious Mr Brougham, will render this more evident. In fig. 7. let the body A have for P an attraction which at the distance of AP is proporof affinity will vary with the distance. Here then is a reason why the affinity of different bodies varies in strength. Sulphuric acid, for instance, has a stronger affinity for barytes than for lime; because when the combinations are formed, the distance between the acid and barytes is not fo great as that between the acid and lime.

But why do the distances differ? If affinity be the fame with gravitation, it must tend to bring the particles nearer one another: And what then prevents the lime from approaching as near the acid as the barytes does? We reply, the figure of its particles. This answer was first given to the question by Buffon, and it is fully adequate to folve the difficulty. The particles of bodies, indeed, are a great deal too minute for us to discover their figure by actual inspection; but the phenomena of crystallization show us that this difference actually exists.

The crystals of every body assume a peculiar figure. Now as these crystals are all formed in the same manner, and by the same law, it is impossible to conceive any other reason for their variety but the difference in the form of the particles which compose them.

But why does one body displace another? When a particle of barytes is brought within a certain distance of a particle of fulphuric acid and lime combined together, affinity acts, and draws them nearer to one another; and the barytes, from its figure, approaches nearer the acid than the lime could, and forms with it a compound, the figure of which is fuch, relatively to that of the lime, that they cannot approach within a finall enough distance of each other to counteract the attraction of the earth. Accordingly no compound is formed; for all that is meant by two particles having formed a compound is, that their attraction for each other is greater than the attraction of the furrounding bodies

Having thus feen that none of the phenomena of afyit finity are inconfident with their resulting from the forces which bring about the phenomena of gravitation, fame, we have a right to conclude, that it is at least highly probable, that all the motions of the corporeal world are produced by the same power which, though not essential to matter, was impressed upon every atom of it by the Great Creator when he formed this universe; and that as the effects of this power are modified according to the fituation of the bodies on which it acts, they are known by the different names of gravity, adhesion, cobesion, and affinity.

GRAVITY is the attraction between bodies fo distant, that the masses alone influence the result, and that the

power may be confidered as placed in the centre of the Affinity. attracting bodies.

Adhesion supposes a distance too small for our fenses. It has been demonstrated to be proportional to the number of touching points, which depends upon the figure of the particles that form the bodies.

Cohesion takes place only between particles of the fame nature. These, instead of touching only in one superficies, as in adhesion, touch in every point where their figure will allow contact: consequently the force of cohesion also must depend upon the figure of the par-

Affinity unites bodies of a different nature, not merely by one fuperficies, as adhefion does, but particle to particle, like cohesion; and the most perfect contact is formed that the figure of the particles will admit. Therefore, in this case also, the intensity depends upon the figure of the particles.

3. If we make the attempt, we shall find that water Saturation will not diffolve any quantity of common falt that we explained. please. Water which refuses to take up any more is faid to be faturated with falt. Neither can we combine any quantity of potals with a given portion of sulphuric acid: we may add as much of it as we please, indeed; but if we evaporate the liquid, in order to obtain the falt in crystals, we shall find that only part of the potass has united with the acid, and that the rest has crystallized separately. From these examples, it must appear evident, that bodies combine with one another by affinity only in certain proportions; or, which is the same thing, that a determinate number of particles of each of the ingredients goes to the formation of an integrant particle of the compound, and that into this integrant no additional particles of either ingredient can be admitted. Let us suppose, for instance, that the particles of fulphuric acid are tetrahedrons, and that the particles of potals are of such a form, that one of them can attach itself to each of the sides of the acid particle: In that case, an integrant particle of sulphat of potass would be composed of five particles, one of acid and four of alkali; for it is evident, that just four particles of potafs would combine with every particle of acid, and that the acid would then be faturated, or, which is the fame thing, would be incapable of receiving any more alkaline particles into combination with it. Let us suppose now, that there is just as much potass as saturates the acid; if more acid be poured in, it cannot enter into combination with the potals, because all the potass is already combined with acid.

Thus it appears evident, from the nature of affinity, that the ingredients in every combination must mutually faturate each other, and that no more of either can

tional to PM; then let P move towards A, fo as to come to the fituation P, and let the attraction here be P'M'; as it is continual during the motion of P to P', MM' is a curve line. Now in the case of the attraction of bodies for one another, I'M is less than P'M'; and consequently MM' does not ever return into itself, and therefore it must go ad infinitum, having its arc between AB and AC, to which it approaches as asymptotes, the abscissa always representing the distance, and the ordinate the attraction at that distance. Let P' now continue its motion to P", and M' will move M'; and if P' meets A, or the bodies come into perfect contact, P"M" will be infinite; fo that the attraction being changed into cohefion will be infinite, and the bodies inseparable, contrary to universal experience; so that P can never come nearer to A than a given distance. Nicholfon's Journal, I. 555.

Affinity. be admitted into the compound than what is necessary to produce this faturation. It follows equally, that there can be no union without faturation, except there be a deficiency in some one of the ingredients: For fuppoing that there is a sufficient number of particles of potals, and that every particle of fulphuric acid requires four of them, as before, for faturation, the very fame cause that produces the union of one, two, or three particles of potals with a particle of acid, must produce the union of all the four.

> Even when there is a deficiency of one of the ingredients, faturation must equally take place; for those particles of acid that happen to be nearest the alkali must still be saturated; because the affinity of all the acid particles for alkali was originally equal, and the difference of the diffance must give the superiority to those that are nearest; and those particles of acid that are once faturated with potals cannot be deprived of it by any of the other particles, otherwise the affinity of fome particles of fulphuric acid for potals would be greater than that of others; which is abfurd.

> It will no doubt be objected to all this, that there are innumerable instances of additional portions of some one of the ingredients being received into a compound after faturation, and that fome fubstances feem to be equally well faturated with different dofes of another. Oxygen, for instance, combines with azot in three different proportions, and forms nitrous gas, nitrous acid, and nitric acid. The metals, too, form, in the fame manner, different oxyds; and a great many instances of the same kind occur among the neutral salts.

But it ought to be remembered, that the conclusions against which these objections are orged, are consequences deduced, we think fairly, from a proposition which we confider as demonstrated, that affinity is a species of attraction (B). These phenomena cannot therefore be admitted as valid objections, except it can be shewn that they are really incompatible with these conclusions. Now that this is not the case, has been shewn, in the most satisfactory manner, by Morveaut. These apparent exceptions are owing to an affinity which exists between the compound as an integrant and one of its ingredients, and are not inflances of various degrees of faturation, but of the formation of new compounds. According to this very ingenious idea, which, we believe, first originated with Bergman, and was full feen in its full extent by Morveau, we have formerly explained in what manner the various metallic oxyds are formed: the first oxyd is a compound of the metal and oxygen; the fecond, of the first oxyd and oxygen; the third, of the fecond oxyd and oxygen; and fo on. In the fame manner we have explained the various combinations of azot and oxygen: and the explanation may eafily be extended to every other case. These apparent objections, then, are not incompatible with the above conclusions, but perfectly confident with them; and confe. Affinie quently they cannot be admitted as of any force.

There is one phenomenon, indeed, which proves, independent of these conclusions, that these combinations are actually formed in the manner we have supposed, and which therefore merits particular attention. The phenomenon is, that the affinity between the two fimple substances is almost always greater than that between the compound and any of its ingredients. The affinity, for instance, between azot and oxygen is greater than that between nitrous gas and oxygen; and the affinity between nitrous gas and oxygen greater than that between nitrous acid and oxygen: For if nitrous gas be mixed with nitric acid, the whole is converted into nitrous acid; but no change whatever is produced when nitric and nitrous acids, or nitrous gas and nitrous acid, are mixed: and every substance which is capable of decomposing nitrous gas is capable also of decomposing nitrous and nitric acids; but many fubstances are capable of decomposing nitrous and nitric acids which have no effect upon nitrous gas. In the same manner, the affinity between fulphur and oxygen is greater than that between fulphurous acid and oxygen: for when fulphur is mixed with fulphuric acid, the whole is converted into fulphurons acid; but no change takes place when fulphur and fulphurous acid, or fulphurous and fulphuric acids are mixed together. A great many instances of the same kind might easily be produced, if these were not fufficient to establish the point. This curious fact affords a very strong proof that the bases, as well as the quantity of oxygen, is different in almost all the vegetable acids. Did the tartarous, oxalic, and acetous acids, for inftance, confift of the same base with various doses of oxygen; were the tartarous composed of the base and oxygen; the oxalic, of tartarous acid and oxygen; the acetous, of oxalic acid and oxygen-in that case, a mixture of acetous and tartarous acids ought to form oxalic acid: but that this does not happen. any one may convince himself by actual experiment.

We do not mean to affirm, that this fact, though it is certainly very often true, holds in all cases; in some, perhaps, the reverse may be true, though we do not recollect at present any instance of that kind.

4. Since the affinity of almost every two bodies for of the each other differs in strength from that between every strength other two, it becomes an important problem to deter. of affinity mine the strength of every affinity in numbers. The folution of this problem would give a clearness and precifion to chemistry equal to that of any other branch of natural philosophy whatever, and enable it to advance with a degree of rapidity hitherto thought unattainable. No wonder, then, that this problem has occupied the attention of some of the most eminent philosophers who have dedicated their time to chemistry.

If the observations formerly made, in order to shew Attempts

that to afcerta

(B) Were any farther proof of this proposition required, we would observe, that cohesion acts as an antagonist to affinity, and may be often rendered fo strong as to prevent affinity from acting with efficacy. Thus alumina and jargonia, when fufficiently heated, become infoluble in acids, without undergoing any other alteration than that of an increase of cohesion by their particles being brought nearer each other; for destroy this cohesion, and they become as soluble as ever. Now it follows from this, that if cohesion be attraction, so must affinity. The experiments of Morveau, to be afterwards mentioned, demonstrate, that adhesion and affinity are produced by the same cause: Consequently, if adhesion be attraction, so must affinity.

i. 560.

upon the difference in the strength of affinities depends upon the different forms of the particles which have an affinity for each other, be conclusive, it is evident, that the certain method of learning the strength of affinities would be to discover the forms of the particles of all bodies. But no method has hitherto been discovered by which it is possible of becoming acquainted with the sigure of the particles of bodies. The experiments indeed of the Abbé Hauy (asterwards to be described) point out a method by which the primary sigure of crystals may be investigated with a good deal of plausibility; but this leaves the knowledge of the sigure of the particles which compose these crystals still uncertain.

As nobody, therefore, has attempted to take this road, in order to calculate the strength of affinities, let us at present consider the different methods which have been proposed for that purpose, that we may see whether any of them will answer the end intended.

Fourcroy proposed to measure the affinity of bodies by the difficulty of separating them after they are combined: but we have no method for measuring this difficulty. Lavoisier and De la Place, indeed, proposed caloric for this purpose; but there are many compounds which caloric cannot separate, and it never produces a separation except by means of its affinity for one or other of the ingredients of the compound. Before caloric, therefore, could be employed as a measure, it would be necessary to know exactly the strength of its own affinity for every other substance; which is just a case of the problem to be resolved.

Macquer supposed, that the affinity of bodies for one another was in the compound ratio of the facility of their anion, and the difficulty of their separation: But as we are in possession of no method of ascertaining either of these, it is evident that this theory, even allowing it to be just (which it certainly is not), could be of no use for affishing us to calculate the force of affi-

Another method has been proposed by the distinguished philosophical chemist Mr de Morveau (c).

In 1713, Dr Brook l'aylor made some experiments on the adhesion of surfaces; and concluded from them, that the force of adhesion might be determined by the weight necessary to produce a separation. But in 1772, Messer La Grange and Cigna, observing that the surfaces of water and oil adhere together, and taking it for granted that these two liquids repel each other, concluded, in consequence, that their adhesion was not owing to attraction; and hence inferred, that adhesion, in general, is always owing to the pressure of the at-

mosphere. This conclusion induced Morveau to exa. Affinity. mine the subject: he found, that adhesion was not affelled by the pressure of the atmosphere; for it required the same weight to separate a disk of glass (30 lines in diameter) from the surface of mercury in the open air, and under an exhausted receiver. He observed, that the same disk adhered to water with a force of 258 grains, and to the folution of potals, though denser, only with a force of 210. This refult not only proved that adhesion was owing to attraction, but made him conceive the possibility of applying this method to the calculation of affinities: For the force of adhesion being necessarily proportional to the points of contact, and this being the case also with affinity, it is evident, that the adhesion and the affinity between the same subflances are proportional, and that therefore the knowledge of the one would furnish us with the ratio of the

Struck with this idea, he constructed cylinders of different metals, perfectly round, an inch in diameter and the same in thickness, and having a small ring in their upper surface, by which they might be hung exactly in equilibrium. He suspended these cylinders, one after another, to the beam of a balance; and after counterpositing them exactly, applied them to a quantity of mercury placed about two lines below them, making them slide along its surface, to prevent any air from lodging between them and the mercury. He then marked exactly the weight necessary to overcome their adhesion, taking care to change the mercury after every experiment. The table of the results is as sollows:

Gold adhe	eres to	mercury	with a	force	of	446 gr.	
Silver,			-	- 1	. !	429	
Tin,						418	
Lead, .			-	- 1		397	
Bismuth,			-	- 1		372	
Platinum,			- 1			282 *	* Morveau,
Zinc,		100-	-		-	204	Ann. de
Copper,					111	142	Chimie, XXV.
Antimony	,		-	-	- "	126	10.
Iron,				-		115	
Cobalt,	-	-	-		-	8	-

The differences of these results cannot be owing to the pressure of the air, which was the same in all; no do they correspond to the densities of the metals; nor can they be owing to accidental differences in the polish of the cylinders, for a plate of rough iron adheres more strongly to mercury than one of the same diameter exquisitely polished;—but they follow precisely the order of affinity, and therefore may be considered as the measure of the strength of the affinity between these different metals and mercury. They surnish us also with a convincing proof, that assimily is attraction, and the same species of attraction with adhesion; and that therefore, if the one be reducible to gravitation, so must the other.

Mr Achard, convinced of the importance of Mr Morveau's observations, made a great many experiments on adhesion, and published the result of them in 1780. He X x proved,

Affinity. proved, that the force of adhesion was not affected by alterations in the height of the barometer, but that its force became weaker as the heat of the fluid increased (D); and that the temperature remaining the same, the force of adhesion increased in the same ratio with the furfaces of the adhering bodies. He made about 600 experiments on the adhesion of different solids and fluids, proved that the force of adhesion did not depend on the densities of the adhering bodies, nor on the different cohesive force of the sluids; and, after a laborious calculation, concluded, that it depended on the figure of the particles of the adhering fluid and folid.

These experiments and calculations of Mr Achard are certainly of importance; and we would have given them here, had not the objects of them been substances which can furnish but few data for calculating the force

of affinities.

This method of measuring the force of affinities feems to be an accurate one, and if it could be applied to every case of affinity, would, in all probability, enable us to solve the problem which we are now confidering: But unfortunately, its application is very limited, being confined to those cases alone in which one of the bodies can be presented in a stuid, and the other in a folid state. Nor can it be applied indiscriminately to all those cases; for whenever the cohesion of any liquid is much inferior to the force of its adhesion to any folid, the separation takes place in the particles of the liquid itself, and consequently we do not obtain the measure of its adhesion to the solid, but of its own cohesion, and that, too, imperfectly. Thus, for instance, Mr Achard found, that fealing-wax adhered to water with a force of 92 grains, and to alcohol only with a force of 533ths; yet we know that fealing-wax has a greater affinity for alcohol than for water; because alcohol diffolves it, which water is incapable of doing. The difference in the result in this instance was evidently owing to the fmaller cohesion of alcohol. Mr Morveau's method must therefore be confined to those cases in which the cohesion of the liquid is stronger than its adhesion to the folid, which may be known by the surface of the folid not being moistened; and to those in which the cohesion is not much inferior to the adhesion; for then, it is evident, that the force of cohesion will be increased as the force of adhesion. Let us suppose, for instance, that two solids, A and B, are made to adhere to the furface of a liquid, and that A can only form an adhesion with 50 particles of the liquid, whilft B adheres to 100; it is evident, that a much smaller force will destroy the cohesion of the 50 particles to which A adheres with the rest of the liquid, than what will be required to destroy the cohefion of the 100 particles united to B with the fame * Morveau, liquid *.

Fincycl. Me-

The method of Mr Morveau, then, may be applied thod. Clim. with accuracy in both cases; and when they occur can only be determined by experiment. It cannot, however, be applied indifcriminately even then; for unless the folid and the fluid be prefented in fuch a state that

no gas is extricated when the adhesion takes place, an Affini accurate judgment cannot be formed of the force of adhefion. When marble (carbonat of lime), for instance, is applied to the furface of fulphuric acid, there is an extrication of gas, which very foon destroys the adhefion, and prevents an accurate refult. Were it possible to employ quicklime inflead of marble, this would be prevented; or if this cannot be accomplished, why might not lime be employed, united with some acid that would not assume a gaseous form, and at the same time has a weaker affinity than fulphuric acid for lime? Why might not the phosphat of lime, for instance, be used, which may be reduced to a state of hardness sufficiently great for the purpose? The extrication of gas, during the application of metals to the furfaces of acids, might be prevented by oxydating their furfaces. It is true, indeed, this could not be done with all the metals, on account of the nature of the oxyd, but it might with feveral; copper, for instance, and filver. It cannot be doubted, that by these methods, and other contrivances that might be fallen upon, a sufficient number of refults might be obtained to render this method of the greatest importance. It is rather furprising, therefore, that it has never been profecuted.

Mr Kirwan has proposed another method of solving And Ki the problem. While he was engaged in his experiments wanon the strength of acids, he observed that the quantity of real acid necessary to saturate a given quantity of each of the bases was inversely as the affinity between the respective bases and the acid; and that the quantity of each of the bases necessary to saturate a given quantity of acid was directly as the affinity between the base and the acid. Thus 100 grains of each of the acids require more alkali for faturation than lime, and more lime than magnefia, as may be feen in the follow-

ing table:

100 grains of Potafs. Soda. Lime. Amm. Mag. Alum. Sulphuric acid 215 165 OIL 90 80 Nitric acid 215 165 96 87 75 65 Muriatic acid 215 158 89 79 71

He concluded, therefore, that the affinity between acids and their bases may be estimated by the quantity of bases necessary for saturation. Thus the affinity between potass and sulphuric acid is 215, and that be-

tween nitric acid and lime 96 *.

We have mentioned formerly, that the principle on Transity which Mr Kirwan calculated the strength of the acids was founded on a mistake. It must follow of course, therefore, that the numbers which refult from it must also be wrong. This Mr Kirwan has acknowledged, and feems to have given up all thoughts of afcertaining the strength of affinities by this method. But before it be abandoned altogether, we wish the following observations were considered.

Bergman long ago established as a principle, under Attemp the name of a chemical paradox, that the stronger any remedy the stronger and the stronger and

⁽D) Strictly speaking, this is owing not so much to a decrease of the force of adhesion, as of that of the cohefion of the fluid itself.

100 parts of potass require 78,5 Sulphuric acid, 64 Nitric;

51,5 Muriatic, 42 Carbonic.

100 parts of foda - 177 Sulphuric, 135,5 Nitric,

135,5 Nitric, 125 Muriatic, 80 Carbonic.

This proposition, which has been admirably illustra-

ted by Morveau +, evidently resolves itself into the two Affinity. following:

1. A base requires the more of an acid for saturation the stronger its affinity for that acid is.

Chim.i. 597.

2. An acid requires the more of any base for saturation the greater affinity it has for that base.

In order to judge of the truth of the first of these propositions, let us examine the following table, drawn up from the experiments of Bergman, Wenzel, and Kirwan.

]	BERGMAN			Wenzel		H	Kirwan	
100 parts of	Sulphuric.	Nitric.	Muriatic.	Sulphuric.	Nitric.	Muriatic	Sulphuric.	Nitric.	Muriatic.
Barytes	15,4		30,8						
Potaís	78,6	64	51,5	82,4	107,7	54	81,8	87,1	78,2
Soda	175	135,5	125	125,8	166,6	83	129,4	136,1	114,2
Lime	143,7	134,4	70,45	147,74	195,6	103,6	141	180	86
Magnefia	173,67	159,25	82,92	181,8	257,15	122,27	170,5	255	104,275
Ammonia				142,42	201,22	96,25	187,5	233	116
Alumina	211,11		220,2	77,7	68,7	38,6		10	

It is evident at first fight, that Bergman's experiments correspond exactly with the proposition. To faturate, according to him, 100 parts of potals, requires 78,6 of fulphuric acid, 64 of nitric, and 51,5 of muriatic acid. There is only one deviation from the proposition in the whole table, and this regards barytes, which, according to him, is faturated with 15,4 of fulphuric and 30,8 of muriatic acid. But Mr Morveau has shewn, by several accurate experiments, that barytes requires much more sulphuric acid for saturation than Bergman supposed J. And Klaproth has shewn, that 100 parts of barytes require 49,2 of strong sulphuric i. 591 acid for faturation *. And Dr Withering's calculation + agrees almost exactly with this; nor does that of Fourcroy differ much from it ‡. Instead of 15,4 of sulphuric acid, therefore, which, according to Bergman, are ne1784 ceffary to faturate 100 of barytes, it should be 42,8.
iv.65 The first and last columns of Wenzel and Kirwan's

The first and last columns of Wenzel and Kirwan's experiments agree equally well with the proposition, but the second deviates from it completely. Wenzel probably might have been misled by the manner of performing his experiments; but the same objection does not seem to lie against those of Kirwan.

It can scarcely be doubted, however, to whatever cause the error is to be imputed, that the numbers in the second column of Mr Kirwan's table are too large. The following experiment of Morveau is sufficient to them this

According to Mr Kirwan's experiments, the proportions of acid and alkali in the four following falts are as

Sulphat of potass Acid 100 Potase 108,7

Sulphat of lime	Acid Lime	100 80,6	,
Nitrat of potals	Acid	100	
Initiat of potats	Potass	83,33	
Nitrat of lime	Acid	100	
TAILIAL OF TIME	Lime	34,4	

Now when fulphat of potass and nitrat of lime are mixed together, a double decomposition takes place, and fulphat of lime and nitrat of potals are formed. Let these two salts be mixed together; let the quantity of fulphat of potals be fuch, that the acid contained in it amounts to 100; and let a more than sufficient quantity of nitrat of lime be added, to faturate the fulphuric acid with lime. It is evident that for that purpose 80,6 of lime must be present; and the quantity of nitric acid combined with these 80,6 must be 234,4. This quantity would require for faturation 195,32 of potals, but there are only 108,7 in the mixture; consequently there ought to exist in the mixture, after the mutual decomposition of the salts, 64,87 of nitric acid in a state of liberty. Such would be the refult, provided Mr Kirwan's numbers were accurate; but the fact is, that no fuch excess of acid exists in the mixture *; and confe- * Ann. de quently the quantity of nitric acid contained in nitrat of Chim. xxv. lime is stated too high by Mr Kirwan. Although 295. therefore Mr Kirwan's tables do not coincide with the proposition which we are considering, this is not to be confidered as a proof of its fallehood; as there is reafon, from the experiment above described, to suspect fome error in the data from which Mr Kirwan calculated the strength of the acids.

The truth of the fecond proposition may be judged of by the following tables:

TABLE II. Quantity of Acid necessary to Saturate 100 Affini Parts of the fix Bases.

1				
	100 parts	Sulph. acid.	Nitric acid.	Mur. acid
	Barytes	42,8	38,7	30,8
	Potafs	18	64	52,9
	Soda	126,7	101,4	79
	Lime	145,7	134,4	87,5
07	Magnesia	176,2	159,25	105,4
	Ammonia	202,6	182,4	127,25

The first of these tables represents the affinity between the same acid and its various bases; and the second that of the bases for the different acids. If it were required to know the ratios of the affinity which different bases have for any particular acid, the first table, supposing it accurate, would give it exactly. In like manner, if it were required to know the ratios of the affinity of the acids for the various bases, we would find them in the second table.

But if we wished to know what was the affinity between one acid and base, compared with that between truckth another acid and a different bate; or if we wanted to of affinity have not the relative but the absolute affinity between two bodies - it is plain that we could not find it in either of the tables; for the absolute affinity must consist of two things, the affinity which the acid has for the bale, and the affinity which the base has for the acid. Now the first table gives us the one of these, and the second the other; fo that in order to represent affinity in abfolute numbers, the two tables must be multiplied into one another. This was the mistake into which Mr Kirwan fell. His method confifted merely in constructing a table like our first, which (supposing the numbers accurate) gave only the affinity between the bases and the fame acid, but left out the affinity between the different acids and the same base; consequently the different columns could not be compared with each other.

It is evident, however, that if the tables were multiplied together in their present state, they could not possibly give an accurate table of affinities. For that purpose, it is necessary to put the same number in the first column of each table, and then to substitute other numbers in the remaining columns, having the same ratio to one another with the numbers in the original columns. This is done in the following tables.

TABLE 1. Ratios of the Affinity of fix Bases for three

	Barytes	Potafs.	Soda.	Lime.	Magn. Amm.
Sulph. acid	100,00	52,85	33,73	29,27	24,3421,12
Nitric acid	100,00	57,43	36,98	28,77	24,28 19,59
Mur. acid	100,00	58,11	38,81	35,70	29,94 24,15

According to BERGMAN. 100 parts of Baryt. Potals. | Soda. Lime. |Magn |Amm. |Alum. Sulp. acid 127,5 56,5 69,5 578 42 473 Nitric acid 148,4 62,8 74,4 74,4 Mur. acid | 324,7 194 178 141,9/120,5 40

	Accor	ding to	WEN	ZEL.	BREEK
oo parts of Bary					Amm. Alum.
Sulp. acid	120,8	379,16	67,2	55	70,2 128
Nitric acid	92,7	60	51,1	38,8	49,7 147,8
Mur. acid	183,8	119,2	96,5	81,7	103,9 259
	Accord	ing to	KIRIV	AN.	24775
100 parts of Baryt.	Potass	Soda.	Lime.	Magn.	Amm. Alum.
Sulp. acid	122,2	77,2	70,4	57,3	53,3
Nitric acid	112	73.8	55,5	39,2	44,8
Mur. acid	168,6	133	112,7	89,9	78,5

It appears that all the table of Bergman agrees with the proposition except the numbers which correspond to fulphat of soda, fulphat of alumina, nitrat of lime, and muriat of soda, which the late experiments of Mr Kirwan have sufficiently shewn to be inaccurate.

Wenzel's table corresponds exactly, except the columns under ammonia and alumina, which Morveau has proved to be inaccurate.

Kirwan's table corresponds exactly, except with regard to the quantity of ammonia necessary to saturate muriatic acid, which does not appear to have been accurately determined by experiment.

Let us therefore take the truth of these two propositions for granted, and let us consider every deviation from them as an error; and let us see whether they will enable us to discover the absolute affinity of sulphuric, nitric, and muriatic acids, for their respective bases.

TABLE I. Quantity of Base necessary to Saturate 100 Parts of the three Acids.

Lime	2927	2653	2143				
Magnefia	2434	2193	1786				
Ammmonia	2112	1763	1515				

On the supposition that the two propositions mentioned above were strictly true, and that the numbers which we fixed upon were precisely the quantities of acid and bate necessary to faturate each other reciprocally, this last table would represent accurately in numbers the strength of the affinities of the three acids for each of the fix bases respectively.

We must acknowledge, however, that the truth of these propositions has not hitherto by any means been sufficiently proved; but a great number of facts concur to render them exceedingly probable, and highly worthy of the attention of chemical philosophers. And we hope that the method proposed by Morveau, and which had been previously practifed by Richter, of verifying theoretical calculations of the composition of the falts, by mixing together two salts which mutually decompose each other, and ascertaining whether the result corresponds with calculation, will be followed out, and that it will be the means of ensuring more accuracy than it has hitherto been possible to obtain.

No one will suspect that any thing which has here been said is meant as a reflection on the ingenious chemists who have attempted to solve this most difficult of all chemical problems, the proportion of the ingredients which enter into the composition of the salts. Mr Kirwan, in particular, is entitled to the greatest praise for the persevering industry with which he has prosecuted

the subject, for the candour which he has displayed, and for the new rout which he has opened to the chemical philosopher. Though this problem has not hitherto been solved, and though the difficulties which furround it are almost infurmountable, we may hope much from the general sense which is at present entertained of its importance, and from the zeal and abilities of those philosophers who have particularly turned their attention to it.

In the mean time, the following table of the flrength of affinities by Morveau, though the numbers be arbitrary, will be found of very great use †.

	Sulph.	Nuric acid.	Muriat.	Acctous	Carbonic scid.
Barytes	66	62	36	28	14
Potals	62	58	32	26	9
Soda	58	50	31	25	8
Lime	54	44	24	19	12
Ammonia	46	38	2 I	20	4
Magnelia	50	40	22	17	6
Alumina	40	36	18.	15	2 (D)

5. Although every chemical combination is produced by the fame general law, yet as their phenomena vary fomewhat according to circumflances, affinities have, 578 for the fake of greater perficiently, been divided into Three classes. These classes may be reduced to three—fimple, classes of afcompound, and disposing affinities.

The first class comprehends all those cases in which Viz simple only two bodies combine together; as, for instance, tul-affinity, phuric acid and potals, oxygen and carbon. The affi nities which belong to this class are known by the name of simple or single affinities. Although one of the substances to be combined happens to be already united with another body, the combination is still reckoned a case of fingle affinity Thus suppose the sulphuric acid previously combined with magnesia, and forming with it the falt called fulphat of magnefia, as foon as potass is presented, the acid leaves the earth (which is precipitated), and unites with the alkali. Even when three bodies combine, it often happens that the union is produced merely by fingle affinity. Thus, when fome potass is dropped into tartarous acid, part of the acid unites with the alkali, and forms tartrite of potals; after this the remainder of the acid combines with the tartrite just formed, and composes a new falt known by the name of acidulous tartrite of potass, or tartar. This is evidently nothing else than two instances of simple affinity immediately following each other.

When more than three bodies are mixed, decompo-Compound fitions and new combinations often take place, which finity,

(D) This table, however, does not correspond quite accurately to all the phenomena. For instance, according to it, sulphat of barytes is not decomposed by carbonat of soda, although the contrary takes place in fact.

Affinity. could not have been produced had the bodies been prefented in a different state. If, for instance, into a solution of fulphat of potass there be poured vitric acid, no decomposition is produced, because the sulphuric acid has a stronger affinity for potals than nitric acid has. For the very same reason, ammonia may be poured into the folution without producing any change. But if nitrat of ammonia be poured in, a decomposition instantly takes place, and two new bodies, fulphat of ammonia and nitrat of potass, are formed. Such cases of decomposition form the fecond class of affinities. They were called by Bergman cases of double elective attraction; a name which is exceedingly proper when there are only four bodies concerned. But as there are often more than four, it is necessary, as Mr Morveau has obferved, to employ some more comprehensive term. We shall therefore call the affinities belonging to this class compound affinities (E); and comprehend under the term all cases where more than three bodies are present, and produce combinations which would not have been formed without their united action. In these cases the affinity of all the various bodies for each other acts, and the refulting combination is produced by the action of those affinities which are strongest. The manner in which these combinations and decompositions take place, was first clearly explained by Dr Black. Let the affinity between potass and sulphuric acid be = 62; that between nitric acid and ammonia = 38; that between the same acid and potals = 58; and that between the fulphuric acid and ammonia = 46. Now, let us suppose that all these forces are placed so as to draw the ends of two cylinders croffing one another, and fixed in the middle in this manner,

It is evident, that as 58 and 46 = 104, are greater than 62 + 38 = 100, they would overcome the other forces and shut the cylinders. Just so the affinity between potass and nitric acid, together with that between sulphuric acid and ammonia, overcomes the affinity between potals and fulphuric acid, and that between nitric acid and ammonia, and produces new combinations.

In all cases of compound affinity, there are two kinds of affinities to be confidered; 1/1, Those affinities which tend to preserve the old compound, these Mr Kirwan has called quiescent affinities; and those which tend to destroy them, which he has called divellent affinities.

Thus, in the instance above given, the affinity be-tween potass and sulphuric acid, and that between nitric acid and ammonia, are quiescent affinities, which endeavour to preserve the old compound; and if they are strongest, it is evident that no new compound can take place. On the contrary, the affinity between potals and nitric acid, and that between fulphuric acid and

ammonia, are divellent affinities; and as they are in this affinity case strongest, they actually destroy the former combinations and form new ones.

Bergman, who published a great many cases of compound affinities, employed to explain them a method somewhat different from this. He would have reprefented the above case in the following manner:

Nitrat of Potals.

Sulphat of Ammonia.

At the four corners of an imaginary square are placed the four substances, so that one acid shall be diagonally opposite to an other. On the right and left side of the square are placed the old compounds, each on the fide of its own ingredients, and above and below are placed the new compounds.

Mr Elliot improved this method of Bergman, by adding numbers expressive of the affinity of the various substances. It is in cases of compound affinity that the ratios of affinities, if we were possessed of them, would be peculiarly useful. For it is evident, that if we knew the strength of affinities in absolute numbers, we would be able to determine before hand all the cases of compound affinity.

If we knew, for instance, that the affinity between the muriatic acid and barytes were = 36; that between the same acid and potass = 32; the affinity between potass and carbonic acid = 9; and that between the fame acid and barytes = 14;—we would be certain, previous even to experiment, that when muriat of barytes and carbonat of potals are mixed, a double decomposition would take place; which we know from experiment to be actually the case.

Muriat of Potafe.

Another instance of decomposition by compound

Sulphat

Supposing Morveau's numbers exact, it follows also, even prior to experiment, that no decomposition takes place when sulphat of lime and muriat of potass are mixed;

for the quiescent affinities are 86, and the divellent

Nor when acetite of lime and muriat of foda are mixed;

because the quiescent affinities are 47, and the divellent only 45. These cases where no decomposition takes place have been called by Morveau cases of *inverse* compound affinity.

Morveau has proposed the following improvements in representing these cases of compound affinities:

When decomposition does not take place, nothing is to be written above and below the square, as in the two last examples. When a new compound remains dissolved, a straight line is to be placed between it and the square, as in the following scheme. Sulphat of Magnelia.

Nitrat of Soda.

When a new compound is precipitated, a line bent downwards in the middle is to be placed between it and the fquare, as in the following scheme:

Sulphat of Potass.

When a new compound is sublimed, the line between it and the square is to be pointed upwards in the middle, thus

When a new compound is partly diffolved and partly precipitated, the line placed between it and the fquare is to affume the following shape:

When it is partly diffolved and partly fublimed, the following is the line to be used:

The third class of affinities has been called by Mr 58r Morveau disposing affinities, because they dispose sub-And dispositances to combine that would not otherwise have done sing affinity it. Suppose, for instance, that sulphur is presented to oxygen gas, it does not manifest any affinity for it; but combine it previously with potass, and it unites with

oxygen with avidity. Its previous union with potafs, in this cafe, difposed it to unite with oxygen. The cause of this curious affinity is not yet well understood. If we consider what it was that prevented the sulphur and oxygen from combining, we shall find, that it can only be its own attraction of cohesion, and the affinity between the oxygen and caloric which are combined. Whatever then diminishes this attraction of cohesion, or of aggregation as it has been called, must facilitate the union

of

Affinity. of the fulphur with oxygen. This is done in some meafure by the potals Belides, if affinity depends upon the figure of particles, it is evident, that there must be an affinity between the new compound and oxygen; but the moment the oxygen approaches within a certain distance of the fulphur, it unites with it, as its affinity is much greater for that substance than for the compound.

The following is another instance of this curious affinity: Sugar, as Lavoisier has proved, is composed of oxygen, hydrogen, and carbon: Now if concentrated fulphuric acid be poured upon fugar, the oxygen and hydrogen combine, and form water, which unites with the acid, and the carbon is precipitated. In this cafe, the prefence of the acid disposed the oxygen and hydrogen to combine. In what manner this new combination is produced, it would not be easy to explain: not by weakening the attraction of cohesion; for we do not see how the acid could produce that effect. The only explanation that can be given, is to suppose that the sulphuric acid, when it approaches within a certain diftance of the oxygen and hydrogen, attracts them; and that this attraction, together with the affinity between the oxygen and hydrogen, is greater than that which produces the combination between the ingredients of the fugar themselves: the consequence of which must be decomposition.

582 De decomposition.
Why bodies 6. We come now to one of the most difficult quesrequire dif-tions in chemistry-Why do bodies require different ferent tem- temperatures in order to unite? and why does the preperatures to fence of caloric in many cases savour or rather produce union, while it prevents or destroys it in others?

Thefe questions were proposed at the end of the fecond chapter of this article; and we referved them for this place, not because we hoped to be able to anfwer them in a satisfactory manner, but because no intelligible answer could be given till the nature of affinity had been previously considered. Some substances, phosphorus, for instance, combine with oxygen at the common temperature of the atmosphere; others, as carbon, require a higher temperature; and others, as hydrogen and azotic gas, do not combine except at a very high temperature. To what are these differences owing?

In answer to this question, we observe, that the attraction of cohesion evidently opposes that of affinity. Those bodies which we present to combine together are generally aggregates, or, which is the same thing, confift of many fimilar particles united by cohefion: for we have no method of separating bodies into their integrant particles, except affinity. Now we can conceive the attraction of cohesion between the particles of a body to be fo great as to prevent them altogether from obeying the impulse of affinity. That this actually happens in some cases cannot be doubted: for if pure alumina be formed into a paste, and heated sufficiently, it becomes so hard that no acid can act upon it; yet its nature is not in the leaft changed: by proper trituration it may be again rendered toluble; and when precipitated from this new folution it has recovered all its original properties. The effect of the fire, then, was merely to increase the cohesion, by separating all the water, and allowing the particles to approach nearer

It is evident, that whatever diminishes the cohesion which exists between the particles of any body, must tend to facilitate their chemical union with the particles

of other bodies: this is the reason that bodies combine Affin more eafily when held in folution by water, or when they have been previously reduced to a fine powder. Now caloric possesses the property of diminishing cohesion. And one reason why some bodies require a high temperature to cause them to combine is, that at a low temperature the attraction of cohesion is in them fuperior to that of affinity; accordingly, it becomes neceffary to weaken that attraction by caloric till it becomes inferior to that of affinity. The quantity of caloric necessary for this purpose must vary according to the strength of the cohesion and of the affinity; it must be inversely as the affinity, and directly as the cohelion. Wherefore, if we knew precifely the force of the cohefion between the particles of any body, and of the affinity between the particles of that body and of any other, we could easily reduce the temperature necessary to calculation.

That caloric or temperature acts in this manner cannot be doubted, if we consider, that other methods of diminishing the attraction of cohesion may be substituted for it with fuccess. A large lump of charcoal, for instance, will not unite with oxygen at so low a temperature as the fame charcoal will do when reduced to a very fine powder; and charcoal will combine with oxygen at a still lower temperature, if it be reduced to its integrant particles, by precipitating it from alcohol, as Dr Priestley did by passing the alcohol through red hot copper. And to shew that there is nothing in the nature of oxygen and carbon which renders a high temperature necessary for their union, if they be prefented to each other in different circumstances, they combine at the common temperature of the atmosphere; for if nitric acid, at the temperature of 60°, be poured upon charcoal powder, well dried in a close crucible, the charcoal takes fire, owing to its combining with the oxygen of the acid *: And in some other situations, * Proof. carbon is fo completely divided that it is capable of Morren combining with the oxygen of the atmosphere, or the oxygen which is the same thing of catching fire at the oxygen which is the same thing, of catching fire at the common temperature: this feems to be the case with it in those pyrophori that are formed by distilling to dryness several of the neutral salts which contain acetous acid +. These observations are sufficient to shew, that + Morror caloric is in many cafes necessary in order to diminish ibid. the attraction of cohesion.

But there is a difficulty still remaining, How comes it that certain bodies will combine with oxygen without the affiffance of any foreign heat, provided the combination be once begun, though a quantity of caloric is necessary to begin the combination? and that other hodies require to be furrounded by a great quantity of caloric during the whole time of their combining with oxygen? Alcohol, for instance, if once kindled, burns till it is quite confumed; and this is the case with oils alfo, provided they be furnished with a wick.

We must observe, in the first place, that we would err very much, were we to suppose that a high temperature is not as necessary to these substances during the whole of their combustion as at the commencement of it; for Mr Monge found, on making the trial, that a candle would not burn after the temperature of the air around it was reduced below a certain point.

All fubstances which continue to burn after being once kindled are volatile, and they burn the easier in proportion

nity. proportion to that volatility. The application of a certain quantity of caloric to alcohol volatilizes part of it; that is to fay, diminishes the attraction of its cohesion so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol; which combines with oxygen in its turn; more heat is given out; and thus the process goes on. Oils and tallow exhibit the very same phenomena; only as they are less volatile, it is necessary to assist the process by means of the capillary attraction of the wick, which confines the action of the caloric evolved to a small quantity of oil, and thus enables it to produce the proper effect. In short, then, every fubstance which is capable of continuing to burn after being once kindled is volatile, or capable of being converted into vapour by the degree of heat at first applied. The reason that a live coal will not burn when suspended insulated in the air, is not, as Dr Hut-Light ton supposed &, because its light is diffipated; but because the coal cannot be converted into vapour by the degree of heat which it contains, and because the cohefion of its particles is too great to allow it to combine with oxygen without some such change. There are fome coals, however, which contain such a quantity of bitumen that they will burn even in the fituation supposed by Dr Hutton, and continue to burn, provided they be furnished with any thing to act as a wick. It is needless to add, that bitumen, like oil, is easily converted into vapour.

But this explanation, instead of removing our difficulties, has only served to increase them: For if caloric only acts by diminishing the attraction of cohefior, and converting these substances into vapour, why do not all elastic fluids combine at once without any additional caloric? why do not oxygen and hydrogen, when mixed together in the state of gas, unite at once and form water? and why do not oxygen and azot, which are constantly in contact in the atmosphere, unite also and form nitrous gas? Surely it cannot be the attraction of cohesion that prevents this union. And if it be ascribed to their being already combined with caloric, how comes it that an additional dose of one of the ingredients of a compound decomposes it? Surely, as Mr Monge has observed, this is contrary to all the

other operations in chemistry.

That the particles of fluids are not destitute of an attraction for each other, is evident from numberless facts. The particles of water draw one another after them in cases of capillary attraction; which is probably owing to the attraction of cohesion. It is owing to the attraction of cohesion, too, that small quantities of water form themselves into spheres: Nor is this attraction so weak as not to be perceptible. If a small plate of glass be laid upon a globule of mercury, the globule, notwithstanding the pressure, continues to preferve its round figure. If the plate be gradually charged with weights one after another, the mercury becomes thinner and thinner, and extends itself in the form of a plate; but as soon as the weights are removed, it recovers its globular figure again, and pushes up the glass before it. Here we see the at-SUPPL. VOL. I. Part I.

traction of cohesion, not only superior to gravita. Affinity. tion, but actually overcoming an external force * * Morveau, And if the workman, after charging his plate of Affinité, glass with weights, when he is forming mirrors, hap-p. 543. pen to remove these weights, the mercury which had been forced from under the glass, and was going to separate, is drawn back to its place, and the glass again pushed up. Nor is the attraction of cohesion confined to folids and liquids; it cannot be doubted, that it exists also in gases; at least it is evident, that there subfifts an attraction between gases of a different kind: for although oxygen and azotic gas are of different gravities, and ought therefore to occupy different parts of the atmosphere, we find them always mixed together; and this can only be ascribed to an attraction. And were we to allow, with Humbolt and several other chemists, that these two gases are chemically combined in atmospherical air, an opinion contradicted by a late experiment in France (F); still the existence of carbonic acid gas in every part of the atmosphere can only be ascribed (if the inaccuracy of the expression may be tolerated) to a kind of cohesion. And whoever has been accustomed to pneumatic experiments must have observed, that small portions of air, as well as water, form themselves into spheres, and that the attraction of cohesion is so strong in gases, that large globules of them often adhere by a fingle point to the bottom of vessels filled with heavy fluids; whereas, had there been no attraction of cohesion, every part of the globule ought to have ascended to the surface of the sluid, except the particles immediately in contact with the vessel. Allowing, then, that there is an attraction of cohesion between the particles of gases, let us see whether that will not affift us in removing the difficulty.

It feems evident, in the first place, that the affinity Explained. between the bases of the gases under consideration and oxygen is greater than their affinity for that dose of caloric which produces their elastic form; for when they are combined with oxygen, the same dose will not separate them again. Let us take hydrogen for an in-stance: The affinity of hydrogen is greater for oxygen than for the caloric which gives it its gaseous form; but the oxygen is also combined with caloric, and there exists an attraction of cohesion between the particles of the hydrogen gas; the same attraction subsists between those of oxygen gas. Now the sum of all these affinities, namely, the affinity between hydrogen and caloric, the affinity between oxygen and caloric, the cohesion of the particles of the hydrogen, and the cohesion of the particles of oxygen-is greater than the affinity between the hydrogen and oxygen; and therefore no decomposition can take place. Let the affinity between

Oxygen and caloric be 50 50 Hydrogen and caloric -Cohesion of oxygen 4 Cohesion of hydrogen 2 Sum of quiescent affinities, 106 The affinity of oxygen and hydrogen,

The quiescent affinities being greater than the divellent affinities, no decomposition can take place. Let

⁽F) Air brought by means of a balloon from a great height in the atmosphere was found to contain less oxygen gas than the same quantity of air near the ground.

Let now a quantity of caloric be added to the oxygen and hydrogen gas, it has the property of expanding them, and of course of diminishing their cohesion; while its affinity for them is so small that it may be neglected. Let us suppose that it diminishes the cohesion of the oxygen 1, and of the hydrogen also 1, their cohesion will now be 3 and 1; and the quiescent affinities being only 104, while the divellent are 105, decomposition would of course take place, and a quantity of caloric would thus be set at liberty to produce the same effects upon the neighbouring particles.

Thus, then, caloric acts only by diminishing cohefion: And the reason that it is required so much in
gaseous substances, and in those combinations into which
oxygen enters, is the strong affinity of oxygen and the
other bases of the gases for caloric; for, owing to the
repulsion which exists between the particles of that subtile substance, an effect is produced by adding large
doses of it, contrary to what happens in other cases.
The more of it is accumulated, the stronger is the repulsion between its particles; and therefore the more
powerful is its tendency to sly off: and as this tendency
is opposed by its affinity for the body and the cohesion of its particles, it must diminish both these attractions.

Though we have thus attempted to explain what has been always considered as one of the most difficult problems in chemistry, we are far from supposing that we have removed every difficulty. Much still remains to be done before the action of light and caloric can be fully understood; and there may be other agents, of whose existence we have not yet even conceived the idea.

One difficulty still remains to be examined. Heat not only produces the combination of some bodies, but also occasions the decomposition of others. How does it act in these cases?

How heat That many of these decomposions are produced by decompose chemical affinity, will be evident from the following exbodies.

When fulphur and arfenic acid are exposed to heat, fulphuret of arsenic is formed + evidently by a kind of compound affinity.

Oxygen Gas.

Caloric 12 Oxygen

60 Arfenic Acid.

Sulphur 50 Arfenic

In the same manner, when nitrat of potass and boracic acid are exposed to heat, the nitric acid is volatilized, and borat of potass is left behind.

By the same compound affinity boracic acid and heat decompose muriat of soda.

In the fame manner, it would be eafy to explain how all the decompositions by the dry way, as it is called, are produced.

But how comes caloric to decompose water after having produced the union of oxygen and hydrogen? The union, we have feen, was probably brought about by the play of opposite affinities; but in the separation, caloric feems to act by its peculiar power, or the repulfion which exists between its particles. When caloric combines with an integrant particle of water, this repulsion must separate the component parts somewhat from one another; consequently it must weaken their affinity; for every increase of distance produces that effect. Now let us suppose that the affinity between oxygen and hydrogen is 105, and that the affinity between caloric and each of these bodies is 50: as soon as the particles of oxygen and hydrogen are so far separated from each other that their affinity is less than 100, they will unite with caloric in preference, because the sum of their affinities for caloric is equal to 100; confequently, whenever that takes place water will be decomposed. Hence we see the reason why more heat is always necessary to produce the decomposition of bodies than what produced their union.

Caloric possesses another singular property, that of changing the compound affinities of bodies, even when

we mean will appear evident from the following examples:

Muriat of ammonia, Carbonat of magnefia, decompose each other at the ordinary temperature of the atmosphere, and form muriat of magnesia and carbonat of ammonia: but, on the contrary.

Muriat of magnetia, and Carbonat of ammonia, decompose each other at a high temperature; for instance, at 212°. The products are muriat of ammonia and carbonat of magne-frum, sia *.

Again, if muriat of foda and fulphat of magnefia be mixed together at a low temperature, for inflance, at zero, they decompose each other, and muriat of magnesia and sulphat of soda are formed; but no decomposition takes place at a temperature above 32°.—Muriat of soda, and sulphat of alumina, exhibit precisely the same phenomena †.

Lastly, sulphat of magnesia and carbonat of ammonia decompose each other at the ordinary temperature; but at 212° the carbonic acid slies off, and the remaining fulfill success form a triple salt \(\frac{1}{2}\).

The last of these phenomena appears owing to the affinity between carbonic acid and caloric, and the two first to the affinity between muriat of ammonia and caloric, for that salt is volatilized.

It would not be so easy to explain the mutual decomposition of muriat of soda and sulphat of magnesia at a low temperature. It is probably connected with the alterations in the distance of the ingredients of chemical compounds, which are produced by the presence and absence of caloric.

ablence of caloric.

From the important part which caloric acts in chemiford's cal combinations, Count Rumford has been lately informed duced to suspect that this subtile sluid is the only agent by which they are produced.

That caloric is a necessary agent in all chemical de-

compositions and new combinations, we very readily al- Affinity. low; because we know no other cause except caloric to prevent the particles of bodies from actual contact; in which case decomposition would be impossible: and if this be the fense in which that ingenious philosopher afcribes chemical combinations to caloric, we very readily agree with him; but if he supposes that caloric is the agent by which the particles of bodies are brought near each other, and the force by which they adhere to one another, we cannot help thinking that he is mistaken: For that bodies, chemically combined, are kept near each other by some sorce, cannot possibly be denied. Now, what is that force? We have faid, after Newton, an attraction between the particles themselves; acknowledging, at the same time, that we are unable to explain what that is.

Count Rumford feems to suppose that there is no such thing as attraction between the particles themselves, but that caloric is the agent which keeps them together. If so, how does caloric perform this office? For our part, we do not pretend to understand it any more than the nature of attraction; nor do we see that it is possible to render it more intelligible. But there is another question of still greater importance, What are the proofs that caloric is the only agent in all cases of chemical combinations? For our part, we can think of no proof that can render this opinion in the smallest degree plausible.

Has this celebrated and candid philosopher confidered this subject with his usual accuracy? If heat be a body, it cannot surely be the cause of affinity unless it be possessed of properties which, so far from being proved, have not even been suspected. On the contrary, if it be a property of matter, what property is it? If it be a peculiar motion, as Count Rumford suspects, we would ask if it be possible for any motion whatever, independent of attraction, to produce the permanent union of two bodies?

PART III. OF DOUBLY COMPOUND BODIES.

THE bodies which confift of combinations of those substances that have been denominated compound, and which, for that reason, we have ventured to call doubly compound bodies, may be reduced to three classes:

Soaps, Neutral falts, Hydrofulphurets.

These shall form the subject of the three following chapters; and we shall finish this part of the article with some observations on crystallization.

CHAP. I. Of SOAPS.

THE compounds into which oils enter without decomposition have been denominated foaps.

Oils are capable of combining with alkalies, earths, and metallic oxyds; they are capable also of combining with several of the acids. There are therefore two classes of soaps; 1. Alkaline, earthy, and metallic soaps, which for the sake of brevity we shall call alkaline soaps; and,

2. Acid foaps. These two classes form the subject of the two following sections.

SECT. I. Of Alkaline Soaps.

As there are a great number of oils, all or most of which are capable of combining with alkalies, earths, and oxyds, it is natural to suppose that there are as many genera of alkaline soaps as there are oils. That there are differences in the nature of soaps corresponding to the oil which enters into their composition, is certain; but these differences are not of sufficient importance to require very particular description. We shall therefore describe all the alkaline soaps together, and notice, as we go along, some of the most important differences resulting from the oily ingredients.

1. Soap of foda, or common foap. The word foat Common (fapo, σαπω) first occurs in the works of Pliny and Gallard foap. len, and is evidently derived from the old German word f.pe (G). Pliny informs us, that foap was first discovered by the Gauls; that it was composed of tallow

(G) Beckmann's History of Inventions, III. 239.—A fimilar word is still used by the common people of Scotland.

Alkaline and afhes; and that the German soap was reckoned the

* Fliny, lib. xviii. Method of

Soap may be prepared by the following process. A quantity of the foda of commerce, which is a carbonat of foda, and which is often called barilla from the name of a plant, by burning which it is procured in great forming it. quantities in Spain, is pounded and mixed in a wooden veffel, with about a fifth part of its weight of lime, flacked and paffed through a ficve immediately before. Upon this mixture a quantity of water is poured, confiderably more than what is sufficient to cover it, and allowed to remain on it for feveral hours. The lime attracts the carbonic acid from the foda, and the water becomes strongly impregnated with the pure alkali. This water is then drawn off by means of a stop-cock, and called the first ley. Its specific gravity should be about

Another quantity of water is then to be poured upon the foda, which, after standing two or three hours, is also to be drawn off by means of the stop cock, and called the fecond ley.

Another portion of water is poured on; and after ftanding a sufficient time, is drawn off like the other

two, and called the third ley.

Another portion of water may still be poured on, in order to be certain that the whole of the foda is diffolved; and this weak ley may be put aside, and employed afterwards in forming the first ley in subsequent ope-

A quantity of oil, equal to fix times the weight of the foda used, is then to be put into the boiler, together with a portion of the third or weakest ley, and the mixture must be kept boiling and agitated constantly by means of a wooden instrument. The whole of the third ley is to be added at intervals to the mixture; and after it is confumed, the fecond ley must be added in the same manner. The oil becomes milky, combines with the alkali, and after fome hours it begins to acquire confiftence. A little of the first ley is then to be added, not forgetting to agitate the mixture constantly. Portions of the first ley are to be added at intervals; the foapy substance acquires gradually greater consistency, and at last it begins to separate from the watery part of the mixture. A quantity of common falt is then to be added, which renders the feparation much more complete. The boiling is to be continued still for two hours, and then the fire must be withdrawn, and the liquor must be no longer agitated. After some hours repose the soap separates completely from the watery part, and fwims upon the furface of the liquor. The watery part is then to be drawn off; and as it contains a quantity of carbonat of foda, it ought to be referved for future use.

The fire is then to be kindled again; and, in order to facilitate the melting of the foap, a little water, or rather weak ley, is to be added to it. As foon as it boils, the remainder of the first ley is to be added to it at intervals. When the foap has been brought to the proper confistence, which is judged of by taking out fmall portions of it and allowing it to cool, it is to be withdrawn from the fire, and the watery part separated from it as before. It is then to be heated again, and a little water mixed with it, that it may form a proper Alkalu paste. It is then to be poured into the vessels proper for cooling it; in the bottom of which there ought to. be a little chalk in powder, to prevent the foap from attaching itself to it. In a few days the soap will have acquired sufficient consistence to be taken out, and formed into proper cakes (11).

The use of the common salt in the above process is to separate the water from the soap; for common falt has a stronger assinity for water than foap has.

Olive oil has been found to answer best for making foap, and next to it perhaps tallow may be placed : but a great variety of other oils may be employed for that purpose, as appears from the experiments of the French chemists above quoted. They found, however, that lintfeed oil and whale oil were not proper for making hard foaps, though they might be employed with advantage in the manufacture of foft foaps. Whale oil has been long used by the Dutch for this last pur

Soap may also be made without the affistance of heat; but in that case a much longer time and a larger

proportion of alkali is necessary.

Manufacturers have contrived various methods of fo-115 fophi phisticating foap, or of adding ingredients which in cation. crease its weight without increasing its value. The most common substance used for that purpose is water; which may be added in confiderable quantities, especially to soap made with tallow (the ingredient used in this country), without diminishing its confistency. This fraud may be eafily detected, by allowing the foap to lie for fome time exposed to the air. The water will evaporate from it, and its quantity will be discovered by the diminution of the weight of the foap. As foap sophisticated in this manner would lose its water by being kept, manufacturers, in order to prevent that, keep their foap in faturated folutions of common falt; which do not diffolve the foap, and at the fame time, by preventing all evaporation, preserve, or rather increase, the weight of the loap. Messrs Darcet, Lelievre, and Pelletier, took two pieces equal in weight of foap tophisticated in this manner, and placed the one in a dry place in the open air, and the other in a faturated folution of common falt. After a month, the first had lost 50 of its weight, the other had gained about 100 parts *. * Ann. de Various other methods have been fallen upon to fophif- Chim. xix. ticate foap; but as they are not, we hope, generally 336. known, it would be doing an injury to the public to describe them here.

Different chemists have analysed soap, in order to as- Proportion certain the proportions of its ingredients; but the re-of its ingredients; fult of their experiments is various, because they used tients. soap containing various quantities of water. From the experiments of Darcet, Lelievre, and Pelletier, it appears that foap newly made and exposed to fale con-

> 9,75 Oil, 1,37 Alkali, 4,87 Water.

Soap is foluble both in water and in alcohol. Its properties as a detergent are too well known to require any description.

It is decomposed by lime, and by compound affinity (1) by sulphat of lime, nitrat of lime, muriat of lime, and probably all the salts which contain lime.

2. Soap of potals. Potals may be substituted for soda in making soap, and in that case precisely the same process is to be followed. It is remarkable, that when potals is used, the soap does not assume a solid form; its consistence is never greater than that of hog's lard. This is what in this country is called soft soap. Its properties as a detergent do not differ materially from those of hard soap, but it is not nearly so convenient for use. The alkali employed by the ancient Gauls and Germans in the formation or soap was potals; hence we see the reason that it is described by the Romans as an unguent.

Some perfons have affirmed that they knew a method of making hard foap with potass. Their method is this: After forming the foap in the manner above defcribed, they add to it a large quantity of common talt, boil it for some time, and the soap becomes solid when cooled in the usual way. That this method may be practifed with success has been ascertained by Messrs Darcet, Lelievre, and Pelletier; but then the hard soap thus formed does not contain potass but soda: for when the common salt (muriat of soda) is added, the potass of the soap decomposes it, and combines with its muriatic acid, while at the same time the soda of the salt combines with the oil, and forms hard soap: and the muriat of potass formed by this double decomposition is dissolved in the water and drawn off along with it *.

Chaptal has lately proposed to substitute wool in place of oil in the making of soap. The ley is formed in the usual manner, and made boiling hot, and shreds of woollen cloth of any kind are gradually thrown into it; they are soon dissolved. New portions are to be added sparingly, and the mixture is to be constantly agitated. When no more cloth can be dissolved, the soap is made †. This soap is said to have been tried with success. It might doubtless be substituted for soap with adventage in several manufactures, provided it can be obtained at a cheaper rate than the soaps at present

Fish, too, have been lately substituted for oil with equal success. The only disadvantage which soap made in this manner is liable to, is a disagreeable smell, from

which it cannot easily be freed.

3. Soap of ammonia. This foap was first particularly attended to by Mr Berthollet. It may be formed by pouring carbonat of ammonia on soap of lime. A double decomposition takes place, and the soap of ammonia swims upon the surface of the liquor in the form of an oil; or it may be formed with still greater ease by pouring a solution of muriat of ammonia into common soap dissolved in water. We have formed it often by

bollet, mixing caustic ammonia and oil *.

Par. It has a more pungent taste than common soap.

The com

4. Soap of lime. This foap may be formed by pouring lime-water into a folution of common foap. It is

infoluble both in water and alcohol. Carbonat of fixed alkali decomposes it by compound affinity †. It inelts with difficulty, and requires a strong heat.

† Thouvene

5. Soap of magnelia. This foap may be formed 593 by mixing together folutions of common foap and ful-Soap of magnelia,

It is exceedingly white. It is unchnous, dries with difficulty, and preferves its whiteness after deficcation. It is infoluble in boiling water. Alcohol and fixed oil diffolve it in confiderable quantity. Water renders its folution in alcohol milky. A moderate heat melts it; a transparent mass is formed, slightly yellow, and very brittle *.

**Bertbollet*

6. Soap of alumina. This foap may be formed by ibid.

594
mixing together folutions of alum and of common foap. Of alumiIt is a flexible foft fubflance, which retains its fupple-na,
nefs and tenacity when dry. It is infoluble in alcohol,
water, and oil. Heat eafily melts it, and reduces it to
a beautiful transparent yellowish mass †.

† Ibid.

7. Soap of barytes retembles almost exactly the foap of barytes, of lime ‡.

8. Soap of mercury.—This foap may be formed by bid.

mixing together a folution of common foap and of cor-of mercurofive muriat of mercury. The liquor becomes milky, r), and the foap of mercury is gradually precipitated.

This foap is vifcid, not eafily dried, lofes its white colour when exposed to the air, and acquires a state colour, which gradually becomes deeper, especially if exposed to the sun or to heat. It dissolves very well in oil, but sparingly in alcohol. It readily becomes soft and sluid when heated *.

9. Soap of zinc.—This foap may be formed by mix- of zinc, ing together a folution of fulphat of zinc and of foap. It is of a white colour, inclining to yellow. It dries fpeedily, and becomes friable †.

10. Soap of cobalt. — This foap, made by mixing ni- of cobalt, trat of cobalt and common foap, is of a dull leaden colour, and dries with difficulty, though its parts are not connected.

Mr Berthollet observed, that towards the end of the Of nickel, precipitation there fell down some green coagula, much more consistent than soap of cobalt. These he supposed to be a soap of nickel, which is generally mixed with cobalt ‡.

11. Soap of tin.—It may be formed by mixing com- of tin, mon foap with a folution of tin in nitro-muriatic acid. It is white. Heat does not fule it like other metallic foaps, but decomposes it ||.

12. Soap of iron—Formed by means of fulphat of Officon, iron. It is of a reddish brown colour, tenacious, and easily fusible. When spread upon wood, it finks in and dries. It is easily foluble in oil, especially of turpentine. Berthollet proposes it as a varnish ¶.

13. Soap of copper.—Formed by means of sulphat of copper, of copper. It is of a green colour, has the feel of a refin, and becomes dry and brittle. Hot alcohol renders its colour deeper, but scarcely dissolves it. Ether dissolves it, liquises it, and renders its colour deeper and more beautiful. It is very soluble in oils, and gives them a pleasant green colour §.

14. Soap of lead.—It may be formed by means of of lead, acetite

⁽¹⁾ In this and the following chapter, compound affinity is not taken always in its strict and proper sense, but is applied to all those decompositions in which the affinities of more than three bodies act.

604

acetite of lead. It is white, tenacious, and very adhefive when heated. When fused, it is transparent, and * Berthellet, becomes somewhat yellow if the heat be increased *

15. Soap of filver .- It may be formed by means of nitrat of filver. It is at first white, but becomes red-Of filver, dish by exposure to the air. When fused, its surface becomes covered with a very brilliant iris; beneath the

1 Ibid. furface it is black +.

16. Soap of gold .- It is at first white, and of the Of gold, confishence of cream. It gradually assumes a dirty purple colour, and adheres to the skin io that it is difficult to effice the impression t.

\$ Ibid. 606 And of

17. Soap of manganele. - It is at first white, but it affumes in the air a reddith colour, owing evidently to manganefe. the absorption of oxygen. It speedily dries to a hard brittle substance, and by liquesaction assumes a brown blackish colour *.

We owe the following refinous foaps to Mr Me-

607

* Ibid.

Soap of tur- 18. Soap of turpentine and potafs. -576. grains of pentine and turpentine were diffolved in 9216 grains of alcohol, and then 576 grains of potass were added. The alcohol was distilled off at a boiling water heat. There remained in the retort 648 grains of a brownish soapy matter, which when spread on glass appeared transparent. There remained also nearly the same quantity of potass dissolved in water. This foap was put in a veffel for fix weeks; during which time 72 grains of folution of potals separated from it. It had assumed the consistence of honey. Its colour was browner. It was completely foluble in water: the folution was milky. It diffolved also in alcohol. It had no difagreeable taste. Vinegar

decomposed it. 608 Soap of benzoin,

19. Soap of benzoin and potafs. - By treating 9216 grains of alcohol, 1728 grains of benzoin, and 576 grains of potals, as above, 1728 grains of a loap were obtained, browner than that of turpentine, of an odour a little aromatic. When left in a cellar for fix weeks, it became folid. Its folution in water was yellowish. Vinegar decomposed it. This compound is the same with Starkeys foap.

609 Of balm of Peru,

20. Soap of balm of Peru and potafs. - 1152 grains of balm, 2304 grains of potals, and 9216 grains of alcohol, produced a foap of a reddish colour, and pretty consistent.

610 Of guaiac,

21. Soap of guaiac and potals. - 1728 gr. of guaiac was diffolved in 18648 grains of alcohol and the folution filtered, and to this 1728 grains of potals were added, and the foap obtained as above. It was folid, of a brown colour at first, which afterwards became green on the furface, but remained unaltered within. Its folution in water was greenish. It had no diagreeable talte. It diffolved in alcohol, and formed a green tincture. Vinegar decomposed it.

611 And of feammony.

22. Soao of feammony and potafs. - By the above process a soap was obtained with scammony pretty confiftent, of a brown colour, foluble in water, and not decomposed by the water of pits from which felenites is obtained. It has no difagreeable tafte. Its folution in ‡ Journ. de alcohol is of a deep amber colour ‡.

Phys. xv. 441.

SECT. II. Of Acid Soaps.

612 Sulfhuric acid may be combined with oils in the Method of following manner: Put two ounces of it into a glass mortar, and add, by little and little, three ounces of the

oil nearly boiling hot, triturating it constantly. A fubflance is obtained of the confishence of turpentine. Diffolve it in about fix onnces of boiling water, and the foap will unite into a mass as the water cools. If it still contain an excess of acid, dissolve it again in boiling water, and continue this process till the foap is perfectly neutralifed.

1. Soap of fulphuric acid and lintfeed oil. - It dif. Ac solves entirely in water. The solution is opaque, of a bluish white colour, viscid, and frothes when agitated. Alcohol diffolves it. The folution is transparent and brown. Potafs decomposes it, forming sulphat of potals. The oil swims on the top, of the confidence of wax. Ammonia decomposes it; and if too much be added it forms foap of ammonia. Magnefia, lime, nitric acid, and mirriatic acid, also decompose it. Distilled, it yielded a few drops of water and an oil, which coagulated, and was of the confiftence of wax.

2. Soap of sulphuric acid and oil of almonds. - So-Of al luble in water; folution milky .- Frothes .- Soluble in oil, alcohol; folution brown and transparent. Potafs, lime, nitric acid, muriatic acid, sulphurous acid (the oil separated assumed the considence of turpentine), tartar, acidulous oxalat of potafs, fal ammoniac, muriat of lead and zinc decompose it. It is not decomposed by vinegar, boracic acid, acetite of ammonia, borax, copper, tin, nor lead. When distilled, there passed over a little water and an oil, which coagulated and fmelt very rancid: there remained behind a coal.

3. Soap of fulphuric acid and olive oil. - It is brown, Of oliv and of the confishence of wax. Solution in hot water il, white, opaque, viscid; frothes. Solution in alcohol transparent and brown. Potals, ammonia, magnefia, nitric acid, muriatic acid, vinegar, nitre, sal ammoniac, acetite of lead and white oxyd of lead decompose it.

4. Soap of sulphuric acid and butter of cocao. - It is Of hun hard, and marbled like Venice foap. Solution in water of coca grey, opaque, viscid; frothes. Solution in alcohol yellow and transparent. Potass, ammonia, nitric, muriatic, and acetous acids, tartar, ful ammoniac, tartrite of potass, acetite of lead, and zinc in powder, decompose it. When distilled, there came over water, an oil that coagulated, and a few drops of a black oil, which also congealed: both were rancid.

5. Soap of fulphuric acid and wax .- It is white, and becomes very hard. Its folution in water is white, and opaque, and frothes: Its folution in alcohol is yellow and transparent. Potals, ammonia, nitric and muriatic acids decompose it.

6. Soap of fulphuric acid and spermaceti - It is Offren brown. It diffolves in water: the folution is milky, cen, viscid, and frothes on agitation. It disfolves in alcohol; the folution is transparent and yellow. It is decompofed by as much alkali as faturates the acid: if more be added, it unites with the oil and forms a new foap. Lime and magnefia decompose it. The oil is also teparated, and appears in the form of a coagulum on adding to the folution nitric acid, muriatic acid, tartar, nitre, nitrat of foda, common falt, and zinc in powder; but not on adding vinegar, tin, lead.

7. Soap of sulphuric acid and oil of eggs .- Its solution of out in water is white, opaque, vilcid; frothes: that in alco- eggs, hol yellow and transparent. Alkalies decompose it; but if too much be added a new foap is formed. Nitric and muriatic acids separate the oil of the confishence of

617

wax, the first yellow, the last a deep brown. Nitre, fal aminoniae, acetite of lead, iron filings, zinc powder, decompose it; vinegar, borax, filings of lead do not.

To unite this acid with the effential oils, three ounces were put into a glass mortar, and four ounces of the oil were added, drop by drop, and care taken to prevent its becoming hot: equal parts of water were then poured on, and the whole heated flowly nearly to the temperature of boiling water: on cooling, the foap united into a brown mass.

8. Soap of fulphuric acid and turpentine. It is brown, . and of the confidence of foft wax. Its folution in water is grey, opaque, viscid; frothes: Its folution in alcohol is brown and transparent. Alkalies decompose it: with too much it forms at the boiling heat a new foap.

Nitric and muriatic acids separated the oil thickened, as did also white oxyd of lead, muriat of lead, muriat of foda, and iron filings; but acetous acid, boracic acid, tartrite of potafs, and tin filings, produced no fuch effect.

9. Soap of fulphuric acid and amber oil.—Its folution in water and alcohol as in the last soap. Alkalies, magnesia, and lime, decomposed it. Nitric and muriatic acids separated the oil of the confishence of wax. Tartar, fal ammoniac, muriat of antimony, acetite of lead, iron filings, decomposed it; vinegar, acetite of ammonia, and lead did not.

Mr Achard, to whom we owe these soaps +, could not succeed in his attempts to form soaps with nitric and muriatic acids.

CHAP. II. Of NEUTRAL SALTS.

THE word falt has been used in chemistry in a very extensive, and not very definite sense. Every body which is fapid, eafily melted, foluble in water, and not

combustible, has been called a falt.

Salts were confidered by the older chemists as a class of bodies intermediate between earths and water. Many disputes arose about what bodies ought to be comprehended under this class, and what ought to be excluded from it. Acids and alkalies were allowed by all to be falts; but the difficulty was to determine concerning earths and metals. Several of the earths possess all the properties which have been ascribed to falts; and the metals are capable of entering into combinations which possess faline properties. It is needless for us to enter into this dispute at present, as we have taken the liberty, in imitation of some of the best modern chemists, to expunge the class of falts altogether, and to arrange those subordinate classes, which are usually referred to it, under distinct heads.

The word neutral falt was originally applied exclud. fively to combinations of acids and alkalies, which were confidered as substances possessing neither the properties of acids nor alkalies, but properties intermediate between the two. But the word is now always taken in a more extensive sense, and signifies all compounds formed by the combination of acids with alkalies, eartlis, or metallic oxyds. In these compounds, the earth, alkali, or oxyd, is denominated the base. Each order of salts is

denominated after the acid which enters into its compo. Sulphats. fition; and every individual falt is diftinguished by fubjoining the name of its base. Thus all the salts into which sulphuric acid enters are called sulphats, and the falt formed by the combination of fulphuric acid and

potals is called sulphat of potals.

It is evident, then, that there must be as many orders of neutral falts as there are acids; and as many falts in each order as there are alkalies, earths, and metallic oxyds, supposing every acid capable of combining with every one of these substances. But besides these simple combinations of one acid and one base, there are others more complex, composed of two acids combined with one base, or two bases combined with one acid, or a neutral falt combined with an acid or a base. These combinations have been called triple falts; and they increase the number of neutral falts very confiderably.

In the following fections we shall take a short view of the properties of the principal neutral falts at prefent known; for this wide and important region of chemiftry is still very far from being completely explored.

SECT. I. Of Sulphats.

SULPHURIC acid is capable of combining with all the alkalies, with alkaline earths, alumina, jargonia, and the greater number of the metallic oxyds. The principal neutral falts which it forms are as follows:

T. Sulphat of potals. - This felt may be formed by Sulphat of faturating diluted potals with fulphuric acid, and then potals. evaporating the folution gently till crystals are formed. It feems to have been known at a very early period by chemists, and a great variety of names were given to it, according to the manner of forming it, or the fancy of the operator. Some of these names were, specificum purgans, nitrum fixum, arcanum duplicatum, panacea bolsatica, sal de duobus, sal polyebrest glaseri, &c.; but it was commonly known by the name of vitriolated tartar till the French chemists called it fulphat of potass, when they formed their new nomenclature in 1787 (K).

When the folution of fulphat of potass is sufficiently to proper-

diluted, it affords by evaporation hexahedral pyramids, ties. or short hexangular prilms, terminated by one or more hexangular pyramids. But these crystals vary much in their figure, according to the care with which they are prepared.

It has a very disagreeable bitter taste. Its specific gravity is 2,298 *.

It is foluble in the temperature of 60° in 16 times its weight of water; in a boiling heat, it is foluble in 5 times its weight +.

According to Bergman, it is composed of 40 parts of acid, 52 parts of alkali, and 8 of water; but according to Kirwan, whose experiment has been already described, it is composed of 45 parts of acid and 55 of alkali.

It fuffers no alteration in the air.

When placed upon burning coals, it breaks into pieces with a noise resembling a number of small explofions succeeding each other at short intervals (1), but fuffers no other alteration. In a red heat it melts.

It has hitherto been applied to little use. It is a

(x) Bergman called it alkali vegetabile vitriolatam, and Morveau vitriol of potafs. (r) This is called decrepitation.

Chim. vi.

purgative, but its difagreeable tafte prevents it from being much employed for that purpose.

It often has an excels of acid, owing, as Mr Bergman and Morveau have very ingeniously explained, to an affinity which exists between this falt and sulphuric acid.

It is decomposed by compound affinity by the following salts:

Nitrat of		Nitrat of filver,
CORPORATION SERVICE PROPERTY.		lead,
Distriction and superior		Acetite of barytes,
-		Muriat of lime +.
-	,	lead ,
-	magnesia,	magnefia?
Company of the Party of the Par	mercury,	- foda ¶.

It is fometimes luminous in the dark, as Mr Giobert has observed *.

Glim. x. 40.

2. Sulphat of foda.—This falt was first discovered by Glauber a German chemist, and for that reason was Sulphat of long known by the name of Glauber's falt. He himfelf called it fal mirabile. It may be prepared by faturating soda with sulphuric acid, but is more usually obtained by decomposing common salt in order to procure muriatic acid.

Its crystals are transparent, and when formed by slow evaporation, are fix-fided prisms terminated by dihedral summits.

Its taste at first has some resemblance to that of common salt, but soon becomes very disagreeably bitter.

It is foluble in 2,67 times its weight of water at the temperature of 60°, and in 0,8 of boiling water.

It is composed, according to Bergman, of 27 parts of acid, 15 of alkali, and 58 of water; but, according to the experiments of Kirwan, of 22 parts of acid, 17 of alkali, and 61 of water.

When exposed to the air, it loses great part of its

water, and falls into a white powder (N).

When exposed to heat, it first undergoes the watery fusion (0), then its water is evaporated, it is reduced to a white powder, and at last in a red heat it melts. Mr Kirwan has observed, that part of the acid, as well as the water, is driven off by the application of a strong heat +.

* Irish; Trans. iv.

This falt is used as a purgative.

It often combines with an excess of acid.

It is decomposed by compound affinity by the following substances.

3. Sulphat of ammonia.—This falt was discovered ammonia.

By Glauber, and called by him fecret fal ammoniae. It was also called vitriolated ammoniae. It may be prepared by faturating ammonia with sulphuric acid.

Its crystals are generally small fix fided prisms, whose planes are unequal, terminated by fix fided pyramids.

It has a sharp bitter tase.

It is foluble in twice its own weight of water at the temperature of 60°, and in its own weight of boiling water.

According to Mr Kirwan, it is composed of 29,7 of alkali, 55,7 of sulphuric acid, and 14,16 of water ||. ||

When exposed to the air, it flowly attracts moisture. Train When heated, it first decrepitates, then melts, and in close vessels sublimes, but with some loss of its alkali †. † Kirm

It has not hitherto been applied to any use.

It is apt to contain an excess of acid.

It is apt to contain an excess of acid.

5. Sulphat of lime. This substance was well known to the ancients under the name of gypfum; but the Sulphat composition of gypfum was not known till Margraf and Macquer analysed it, and proved that it was composed of sulphuric acid and lime. The artificial composed

(M) Most of these double decompositions in this and the following sections are inserted on the authority of Morveau. See his table of Assinity, page 360 of this article.

(N) This is called efforescing.

(O) When substances melt by means of the water they contain on the application of heat, they are said to undergo the watery sussen.

I.

pound formed by the union of these two bodies was formerly called felenite.

It is found crystallized in various forms, sometimes transparent and sometimes opaque; and when pure it is of a white colour.

It has a flightly naufeous tafte, scarcely perceptible except by drinking a glass of water impregnated with

It is foluble in 500 parts of water at the temperature of 60°, but much more foluble in boiling water.

It is composed, according to Bergman, of 46 parts of acid, 32 of earth, and 22 of water; according to the late experiments of Mr Kirwan, when so far dried as still to retain its glassy appearance, it contains 48 of acid, 34 of earth, and 18 of water; which differs very little from the determination of Bergman.

It is not affected by exposure to the air.

It is foluble in fulphuric acid.

When exposed to heat, it undergoes a kind of watery fusion, but afterwards it cannot be melted by the strongest heat. In a clay crucible indeed it suses at 130° Wedgewood, owing evidently to the presence of the clay.

When heated red hot and cooled, it is called *plufter* of Paris; a substance so useful for casting moulds, &c. on account of its property of becoming solid almost immediately when reduced into a paste with water.

By compound affinity it is decomposed by the follow-

ing substances:

6. Sulphat of firontites. This falt, first formed by Dr Hope, is a white powder destitute of taste. It is soluble in 3840 parts of boiling water. Sulphuric acid dissolves it readily when affished by heat, but it is precipitated by the addition of water to the solution †.

7. Sulphat of magnetia. This falt was first observed in the springs at Epsom in England by Grew in 1675; but Dr Black was the first who accurately ascertained its composition. It has been called Epsom falt, fal catharticus amarus, and Seydler salt.

It crystallizes in quadrangular prisms, whose plains are equal, surmounted by quadrangular pyramids.

It has an excessively bitter taste.

At the temperature of 60° it is foluble in its own weight of water, and in \(\frac{1}{4}\ths \) of its weight of boiling water. The volume of water is increased \(\frac{1}{4}\th \) by adding the falt \(\frac{1}{4}\th \).

It is infoluble in alcohol.

It is composed, according to Bergman, of 19 parts of earth, 33 of acid, and 48 of water; according to Mr Kirwan, of 17 parts of earth, 29,46 of acid, and 53,54 of water.

When exposed to the air it effloresces, and is reduced

to powder.

When exposed to heat it undergoes the watery fufion, and by increasing the temperature its water is eva-SUPPL. Vol. I. Part I.

porated, but it cannot be decomposed by means of Sulphats heat.

It is fometimes employed as a cathartic, but its chief use is to furnish magnesia by its decomposition.

It is decomposed by compound affinity by the fol-

quantity of magnefia was precipitated, and a confiderable quantity more on the addition of another dose of ammonia; but farther additions had no effect. From the magnefia precipitated, it appeared that 38 parts of the sulphat had been decomposed. There remained, therefore, 62 parts in solution, mixed with a large quantity of ammonia. By evaporation, 92 parts of a white transparent ihomboidal salt were obtained, evidently composed of sulphuric acid, ammonia, and magnefia, in the proportions that would have formed 62 parts of sulphat of magnefia and 30 of sulphat of ammonia, and probably consisting of a combination of these two sulphates.

9. Sulphat of alumina. This falt may be formed by 211. dissolving alumina in fulphuric acid. It has an astrin-635 gent taste, is very soluble in water, and crystallizes in Sulphat of thin plates which have very little consistence *. Little alumina. attention has hitherto been paid to this falt, which was *Vauquelin, Ann. de never properly distinguished from alum till two memoirs, Chim. xxii. one by Vauquelin and another by Chaptal, on the na-277. and ture of alum, made their appearance in the 22d volume *Chaptal*, of the *Annales de *Chimie*. This salt generally contains an excess of acid, and is not neutralized without confiderable difficulty †.

10. Sulphat of alumina and potals, or alum. The 277.
στυπτηρια of the Greeks, and the alumen of the Romans, was a native substance, which appears to have been nearly related to green vitriol or fulphat of iron; and which consequently was very different from what we at present denominate alum. From the researches of Professor Beckmann, it appears that we owe the discovery of alum to the Asiatics; but at what period, or by what means, the discovery was made, is altogether unknown.

It continued to be imported from the East till the 15th century, when a number of alum works were established in Italy. In the 16th century it was manufactured in Germany and Spain; and during Queen Elizabeth's reign an alum work was established in England by Thomas Chalomer.

by Thomas Chalomer.

The alum of commerce is usually obtained from earths containing sulphur and clay, or sulphuric acid and clay.

The composition of alum has been but lately under-its compo-Z z frood sition,

⁽P) Only below the temperature of 32°. Scheele, Gren, Ann. de Chim. xxiii. (Q) Only below the temperature of 212°. Fourcroy, Ann. de Chim. ii. 291.

Sulphats. Atood with accuracy. It has been long known, indeed, that one of its ingredients is sulphuric acid (R); and the experiments of Geoffroy, Hellot, Pott, Margraf, and Macquer, proved incontestibly that alumina is another ingredient. But fulphuric acid and alumina are incapable of forming alum: Manufacturers knew, that the addition of a quantity of potals, or of ammonia, or of fome fubftance containing these alkalies, is almost always necessary; and it was proved, that in every case in which fuch additions are unnecessary, the earth from which the alum is obtained contained already a quantity of potafs. Various conjectures were made about the part which potass acts in this case; but Chaptal and Vauquelin appear to have been the first chemists that afcertained by decifive experiments that alum was a triple falt, composed of sulphat of alumina and of potass united together (s).

638 And properties.

§ Ibid.

Alum crystallizes in large octahedrons, composed of two tetrahedral pyramids, applied to each other at their

It has a sweetish and astringent taste, and always reddens the tineture of turnfol.

* Neumann It is foluble at the temperature of 60°, in from 10* and Chaptal to 15+ times its own weight of water, according to its and Chaptal. purity; pure alum being most insoluble. Seventy-five # Bergman. parts of boiling water dissolve 100 of alum #.

A hundred parts of alum contain, according to Kirwan, 17,62 parts of acid, 18 of earth (and alkali), and

Kirwan's 64,38 of water ||. Min. ii. 14.

When exposed to the air it effloresces slightly.

When exposed to a gentle heat it undergoes the watery fusion. A strong heat causes it to swell and foam, and to lose about 44 per cent. of its weight, confisting chiefly of water of crystallization f. What remains is called calcined or burnt alum, and is fometimes used as a corrofive.

Alum is of great importance as a mordant in dyeing, and is used also in several other arts.

By compound affinity it is decomposed by the sollowing falts.

Acetite of potals,
foda,
lime,
ammonia,
magnefia,
Carbonat of barytes,
potafs,
foda,
lime,
ammonia,
magnefia.

Homberg's pyrophogus.

If three parts of alum and one of flour or fugar be

melted together in an iron ladle, and the mixture dried sal till it becomes blackish and ceases to swell; if it be then pounded small, put into a glass phial, and placed in a fand-bath till a blue flame iffues from the mouth of the phial, and after burning for a minute or two be allowed to cool (T), a substance is obtained known by the name of Homberg's pyrophorus, which has the property of catching fire whenever it is exposed to the open air, especially if the air be moist.

This substance was accidentally discovered by Homberg about the beginning of the 18th century, while he was engaged in his experiments on the human faces. He had distilled a mixture of human fæces and alum till he could obtain nothing more from it by means of heat; and four or five days after, while he was taking the residuum out of the retort, he was surprised to see it take fire spontaneously. Soon after Lemery the Young. er discovered that honey, sugar, slour, or almost any animal or vegetable matter, could be substituted for human fæces; and afterwards Mr Lejoy de Suvigny shewed that feveral other falts containing fulphuric acid might be fubilituted for alum *. Scheele proved, that * Set alum deprived of potafs was incapable of forming py. quer rophorus, and that fulphat of potass might be substituted for alum +. And Mr Proust has shewn, that a num-+ sid ber of neutral falts, composed of vegetable acids and al-line, kalies, or earths, when distilled by a strong fire in a retort, left a refiduum which took fire spontaneously on exposure to the air.

These facts have thrown a great deal of light on the nature of Homberg's pyrophorus, and enabled us in fome measure to account for its spontaneous inflammation. It has been afcertained, that part of the fulphuric acid is decomposed during the formation of the pyrophorus, and of course a part of the alkaline base becomes uncombined with acid, and the carbon, which gives it its black colour, is evidently divided into very minute particles. It has been afcertained, that during the combustion of the pyrophorus a quantity of oxygen is absorbed. The inflammation seems to be owing to a disposing affinity. Part of the carbon and of the sulphur attract oxygen from the atmosphere, in order to combine with the potafs, and the caloric difengaged produces a temperature sufficiently high to kindle the rest

of the carbon.

Alum is capable of combining with alumina, and of forming what has been called alum faturated with its earth, which is an infoluble, taftelefs, earthy-like fubstance.

It is capable also, as Chaptal informs us, of combining with feveral other bases, and of forming many triple falts, which have never yet been examined with attention *.

1 1. Gbinit

(R) Some chemists have thought proper to call the fulphuric acid, obtained by distilling alum, spirit of alum. (s) This they did in the two memoirs above quoted, and which were first published in the 22d volume of the Annales de Chimie. An account of Vauquelin's memoir has been already given under the article ALUM in this Supplement. Chaptal's memoir is no less interesting. This celebrated chemist appears, from the sacts stated in the 23d volume of the Annales, p. 222. to have made his discovery before Vauquelin; who, however, was ignorant of what Chaptal had done, as he informs us in the Ann. de Chim. xxv. 107. that his paper was read to the Institute a fortnight before that of Chaptal's came to Paris. He informs us, too, that Descroifilles had long before made the same discovery, and that he had published it in Berthollet's Art de la Teinture.

(T) Care must be taken not to keep it too long exposed to the heat.

11. Sulphat of jargonia (v). In order to combine jargonia with acids, they should be poured upon it while it is yet moist, after being precipitated from some of its folvents; for after it is dry, acids do not act upon it without difficulty. By this method fulphat of jargonia is easily formed. It is white, and without fensible tafte. Heat expels the acid from it, and the jargonia remains in a state of purity. At a high temperature charcoal converts it into a fulphuret, which is foluble in water, and which, by evaporation, furnishes crystals of hydrofulphuret (T) of jargonia +.

Klaproth informs us, that with excess of acid fulphat of jargonia forms transparent stelliform crystals, fo-

luble in water, and having an altringent talte †.
12. Sulphat of iron. There are two fulphats of iron, which were first accurately distinguished by Mr Proust. The one contains the green oxyd, the other the red oxyd of iron. We shall, in imitation of Mr Proust, denominate them from their colours.

The green fulphat of iron .- This falt, which is compoled of fulphuric acid and green oxyd of iron, is found native, and was known to the ancients. It is mentioned by Pliny under the names of mify, fory, calchantum *. It was formerly called green vitriol.

It is generally prepared by exposing native sulphuret of iron, a very abundant mineral, to air and moisture.

Its crystals are of a light green colour, and in the form of rhomboidal parallelopipeds.

It has a sharp astringent taste.

It is toluble in fix times its weight of water at the temperature of 60°, and in 3ths of its weight of boiling water +.

of acid, 23 of oxyd, and 38 of water; but according Sulphate to Mr Kirwan, of 26 parts of acid, 28 (u) of oxyd, and 46 of water.

When exposed to the air, it effloresces; but if it be moistened, it is gradually converted into red fulphat of

When heated, it first assumes a yellow colour, loses its water and its acid; if the heat be increased, nothing remains but a yellow powder.

The Pruffic alkali precipitates from the folution of this falt a white powder, which gradually becomes blue by attracting oxygen f.

It is used in dyeing, and in making ink, &c. It is decomposed by compound affinity, by Nitrat of filver,

* Ballen and Muriat of foda *. The red fulphat of iron may be formed by exposing Ann. de a folution of green fulphat to the air, or by treating it Chim. xi. with nitric acid. It was formerly called mother water of 320 vitriol.

Little is known of its properties, except that it is of iron. deliquescent, incrystallizable, and soluble in alcohol.

It was first accurately examined by Mr Proust. The green fulphat of iron generally contains some of it, which may be separated by means of alcohol.

It is alone capable of forming Prussian blue with the Pruffic acid, and of striking a black colour with the gallie acid +.

We have observed, that when it is diluted with wa-per, Nichola ter, and an excess of sulphuric acid is poured in, it is fon's Jouragain flowly converted into green fulphat.

g water †.

It is infoluble in alcohol.

According to Bergman, it is composed of 39 parts

13. Sulphat of zinc. — I'his falt, according to the 643
best accounts, was discovered at Rammelsberg in Ger-Sulphat of many, about the middle of the 16th century. Many

(v) Jargonia, or, as the French chemists call it, zirconia, has been discovered in great abundance in France by Morveau, who found that the hyacinths of Expailly contained more than half their weight of it. From Vauquelin's analysis they appear to be composed of

32 parts of filica, 64 oxyd of iron.

Jargonia has been examined with great care by these two philosophers, the experiments of Klaproth have been confirmed, and several new properties of it have been discovered. Perhaps a more detailed account than we have litherto given of this new earth may not be unacceptable to our readers.

Jargonia is a white powder, its specific gravity is considerable, it has a feel refembling that of silica, it has no tafte, and is infoluble in water. When separated from its folutions by pure alkalies, it retains, when exposed to the air to dry, a pretty confiderable quantity of water, which renders it transparent, and gives it a resemblance to gum arabic both in its colour and fracture.

When exposed to the heat of the blow-pipe it does not melt; but Vauquelin melted it by exposing it surrounded with charcoal in a porcelain crucible to an intense heat for an hour and a half. Its specific gravity was then 4,35, its colour was grey, and its hardness such that it was capable of scratching glass. It melts with borax, and forms a transparent and colourless glass; but phosphat of soda and the fixed alkalies do not attack it.

It is infoluble in the fixed alkalies, has very little affinity for carbonic acid, and is precipitated from its folu-

tions together with iron by the Prussic alkali.

Its affinities, as far as they have been ascertained by Vauquelin, are as sollows:

Vegetable acids, order unknown, Sulphuric acid,

Muriatic, Nitric.

See upon this subject the Memoirs of Morveau and Vauquelin, Ann. de Chim. xxi. 72. and xxii. 179.

(T) These curious salts form the subject of the next chapter. u) Perhaps the quantity of oxyd is somewhat over-rated here; for before it was examined by Mr Kirwan, it had assumed a red colour: it must therefore have been converted into the brown or red oxyd by attracting oxygen from the atmosphere.

Sulphats. afcribe the invention to Julius Duke of Brunswick. Henkel and Newmann were the first chemists who proved that it contained zinc; and Brandt first ascer-

† Beckmann', tained its composition completely ‡. It is generally Hist. of In- formed for commercial purposes from sulphuret of zinc ventions, art. or blende, as it is called. This falt is called also white

ture of 60°; but in a much smaller quantity of boiling sub

It is composed, according to Bergman, of 46 parts * Buye of acid, 26 of oxyd of copper, and 28 of water. Kirwan supposes it to contain 27,68 of acid, 35 of oxyd, and 37,32 of water ‡.

When exposed to the air, it effloresces, and is cover-23.

ed with a yellowish grey powder.

It requires a very strong heat to decompose it. It has the property of communicating a green colour to flame.

It is used in the preparation of several paints, and for a variety of other purpoles.

It is decomposed by compound affinity, by acetite

20. Sulphat of bifmuth.—Little is known of this sulpha falt, except that it is with difficulty crystallized, and is bifmu! very deliquescent.

21. Sulphat of antimony. - This falt does not cry- Antim

stallize. It is easily decomposed by heat.

22. Sulphat of arsenic.—This salt is scarcely known. And It does not appear to be crystallizable. It is decom-

posed by water.

23. White fulphat of mercury. - This falt may be White formed by boiling together two parts of mercury and phat of three of concentrated sulphuric acid, and stopping the mercun, process whenever the mercury is converted into a white mass. This mass, in order to remove the excess of acid, is to be washed repeatedly with small portions of water, till it ceases to redden turnsole. The sulphat of mercury, thus obtained, is very white. Its crystals are either small plates or prisms. Its taste is not very cauflic. It is foluble in 500 parts of water at the temperature of 55°, and in 287 parts of boiling water. It is composed of 83 parts of white oxyd of mercury, 12 of sulphuric acid, and 5 of water *. It is not altered * Four by exposure to the air. Heat decomposes it.

This fulphat is capable of combining with a new Chim. 1 portion of acid: It was in that state before it was wash. 299. ed with water. This falt, which may be called acidulous white fulphat of mercury, has a very caustic taste, and is corrosive. It reddens vegetable blues. It is soluble in 157 parts of water at the temperature of 550, and in

33 parts of boiling water to

24. Yellow sulphat of mercury. This falt may be ibid. obtained by continuing to boil the preceding mixture of bis mercury and fulphuric acid till the mercury affumes a yel-Yellow what what we will be the preceding mixture of bis mercury affumes a yel-Yellow with the preceding mixture of bis mercury and fulphuric acid till the mercury affumes a yel-Yellow with the preceding mixture of bis mercury and fulphuric acid till the mercury affumes a yel-Yellow with the preceding mixture of bis mercury and fulphuric acid till the mercury affumes a yel-Yellow with the preceding mixture of bis mercury and fulphuric acid till the mercury affumes a yel-Yellow with the mercury affur the yellow with the y low colour. It appears to be composed of yellow oxyd mercul of mercury and a small portion of sulphuric acid. It is foluble in 2000 parts of water at the temperature of 55°, and in 600 parts of boiling water. The folution is colourless. It was formerly called turbith mineral to + Fourth

25. Sulphat of ammonia and mercury. - This triple ibid. falt may be formed by pouring ammonia into a folution of fulphat of mercury. If only a small quantity of am-Sulpha monia be used, a copious blackish precipitate takes and monia place, part of which is converted into running mercury ry. by exposure to light; and consequently is black oxyd of mercury; the remaining part is the triple falt. If a large quantity of ammonia be used, only the black oxyd

(v) There is evidently some mistake in this statement; it does not correspond with what he says elsewhere. (w) Mineralogy, ii. 24. We do not understand this statement.

(x) Westfeld, indeed, obtained it; but he mistook it for sulphat of magnesia.

pats. is precipitated; for the triple falt is rendered much more foluble by an excess of ammonia. As this excess evaporates, the falt crystallizes. The crystals are polygons, very brilliant and hard. It has a sharp, austere, metallic taste. It has no peculiar odour. It is scarcely foluble, except with excess of ammonia. It is compofed, according to Fourcroy's analysis, of 18 parts of fulphuric acid, 33 of ammonia, and 39 of oxyd of mercury. Heat decomposes it. The products obtained by distilling it are, a little ammonia, azotic gas, a little pure mercury, some fulphite of ammonia; and there remains 1 reroy, yellow sulphat of mercury *.

This triple falt may be formed also by pouring ammonia upon acidulous fulphat of mercury, or on yellow

fulphat of mercury †.

26. Sulphat of filver.—This falt is formed by pouring fulphuric acid on oxyd of filver. Its crystals are fmall needles. It melts when exposed to a strong heat, but does not sublime.

It is decomposed by muriat of lead ‡.

27. Sulphat of gold.—This falt is unknown.

28. Sulphat of platinum.—Unknown.

29. Sulphat of tungsten .- Probably no such combination is possible.

30. Sulphat of molybdenum. - Probably impossible.

31. Sulphat of uranium. - This falt was first format of ed by Mr Klaproth. He formed it by pouring sulphus ric acid on the oxyd of uranium. Nothing farther is known of it, except that its crystals are small, and of a yellow colour.

32. Sulphat of titanium. This falt was first formed by Mr M. Gregor. It does not appear, from Klaproth's

experiments, to be crystallizable.

33. Sulphat of tellurium.-When one part of tellurium is mixed cold in a well stopped vessel with a hundred parts of concentrated sulphuric acid, the latter gradually affumes a beautiful crimfon red colour: when a fmall quantity of water is added, drop by drop, the colour disappears, and the metal is precipitated in the torm of black flakes. The folution is destroyed by heat, the colour disappears, and the metal leparates in the state of a white oxyd. When sulphuric acid is diluted with two or three parts of water, and a fmall quantity of nitric acid is added, it dissolves a considerable quantity of telluriam. The folution is transparent and colourless, and is not decomposed by the addirent and colourlets, and is not decome of the street of water to g i. 30.

SECT. II. Of Sulphites.

SALTS composed of sulphurous acid united respectively with alkalies, earths, or oxyds, are called fulphites. Those hitherto examined are the following:

1. Sulphite of potals.—This falt was first formed by phite of Stahl; but was first accurately described by Berthollet,

Fourcroy, and Vauquelin.

It may be formed by paffing fulphrurous acid into a faturated folution of carbonat of potafs till all effervefcence ceases. 'I'he solution becomes hot, and crystal-

Fourcroy, lizes by cooling *.

317. bid. .

Its crystals are white and transparent; their figure that of rhomboidal plates. Its crystallization often pres Four. fents small needles diverging from a common centre +.

Its taste is penetrating and sulphurous. At the common temperature of the atmosphere, it is soluble in it own weight of water, but much more soluble in boiling water.

When exposed to the air, it effloresces, becomes Sulphites. opaque and hard, and is gradually converted into fulphat of potass by absorbing oxygen.

When exposed to a sudden heat, it decrepitates, loses its water: at a red heat some sulphurous vapours are emitted; at last a portion of sulphur separates, and the refiduum is sulphat of potals, with a slight excels of al-

Nitric and oxy-muriatic acids convert it into fulphat

of potals by imparting oxygen.

It decomposes the oxyds of gold, filver, mercury, the red oxyd of lead, the black oxyd of manganese, and the brown oxyd of iron. When the green oxyd of ironand the white oxyd of iron are boiled with it in water, and an acid added, a precipitate takes place of thefo bodies united to some sulphur, and the salt is converted into a sulphat: at the same time sulphurated hydrogen gas is emitted.

By compound affinity it is decomposed by

All falts with base of soda, except the borat and ear-

All metallic falts except carbonats;

All neutral falts whose acid has a stronger affirity thid. for potass than sulphurous acid has +.

2. Sulphite of foda .- This falt was first accurately Sulphite of described by Fourcroy and Vauquelin.

It is white and perfectly transparent. Its crystals are four-sided prisms, with two very broad sides and two very narrow ones, terminated by dihedral pyramids.

Its tafte is cool and sulphurous.

It is foluble in four times its weight of cold water, but it is more soluble in hot-water.

It is composed of 18,8 parts of soda, 31,2 of acid, and 50 of water.

By exposure to air, it effloresces, and is slowly converted into a fulphat.

When exposed to heat, it undergoes the watery fufion, and afterwards exhibits precifely the same phenomena as the fulphite of potals.

Metallic oxyds and falts affect it precisely as they.

do sulphite of potals.

It is decomposed by compound affinity by carbonat of potals, and the other falts which decompose sulphite

3. Sulphite of ammonia. This falt was first describing phite of

bed by Fourcroy and Vauquelin . It crystallizes in fix fided prilms terminated by fix- I Fources,

fided pyramids. ed pyramide.

Its taste is cool and penetrating like that of the fon's four. other ammoniacal falts, but it leaves a sulphurous im- ; 317.

pression in the mouth.

It is soluble in its-own weight of cold water. Its solubility is increased by heat.

It is compeled of 29,07 parts of ammonia, 60,06 of acid, and 10,87 of water.

When exposed to the air, it attracts moisture, and is foon converted into a fulphat.

Heat volatilizes it without decomposition.

Its habitudes with metallic oxyds and falts are nearly the same with those of the above described sulphites, while of only it is capable of forming with feveral of them triple barytes.

4. Sulphice of barytes.—This falt was first described thin it. 57. by Berthollet 1.

It is incrystallizable; it has no perceptible taste; and and Vaugueis perfectly infoluble in water *.

It

Sulphites.

Tacid, and 2 of water.

It does not eafily change into a sulphat by exposure to air; but heat produces this effect ‡.

5. Sulphite of lime. This falt was first described by Sulphite of Berthollet ||.

Its crystals are six sided prisms, terminated each by a very long pyramid *.

It has fearcely any taste; however, when kept long and Vauque in the mouth, it communicates to the tongue a tafte which is manifeftly fulphurous.

> It is very sparingly soluble in water, except with excess of acid.

It is composed of 47 parts of lime, 48 of sulphurous acid, and 5 of water.

By contact of air it is converted into a sulphat, but very flowly.

Heat converts it into a sulphat by depriving it of a portion of fulphur.

It is decomposed by compound affinity by Carbonates of alkalies, Fluats of alkalies,
Phosphats of alkalies, Most metallic salts *.

6. Sulphite of magnesia.—This salt was first descri-

* Ibid. 664 Sulphite of bed by Fourcroy and Vauquelin.

Its crystals are white and transparent, and in the form of depressed tetrahedrons.

Its taite is mild and earthy at first, and afterwards

It is sparingly soluble in water, except when there is an excels of acid.

It is composed of 16 parts of magnefia, 39 of acid, and 45 of water.

It becomes opake when exposed to the air; is very

flowly converted into a fulphat.

By exposure to heat, it softens, swells up, and becomes ductile like gum; a strong heat decomposes it altogether.

It is decomposed by Alkaline falts,

4 Fourcroy, Earthy falts, except those of alumina +. and Vauque 7. Sulphite of alumina .- First formed by Berthollet It does not crystallize, but is converted into a soft Su'phite of ductile mass. It is not soluble in water, but becomes alumina. abundantly so when there is an excess of acid.

It is composed of 44 parts of alumina, 32 of acid, and 24 of water.

Heat decomposes it ¶. ¶ Fourcroy

and V.suque-8. Sulphite of iron.—It was first formed by Berthollin. 666

Its crystals are white, and have but very little of the Sulphite of styptic taste of iron falts *. iron.

Berthollet also formed the sulphites of zinc and tin, * Ann. de Chim. ii. 58 but he has not described them.

SECT. III. Of Nitrats.

Those falts, in the composition of which the nitric

acid forms one ingredient, are called nitrats.

1. Nitrat of potals, nitre, or faltpetre. - As this falt is produced naturally in confiderable quantities, particularly in Egypt, it is highly probable that the ancients were acquainted with it; but scarcely any thing certain can be collected from their writings. If Pliny mentions it at all, he confounds it with foda, which was known by the names of nitron and nitrum. It is certain, however, that it has been known in the east from

It is composed of 59 parts of barytes, 39 parts of time immemorial. Roger Bacon mentions this falt in Nitral, the 13th century under the name of nitre.

It crystallizes in slender oblong hexagonal prisms, often striated, terminated by hexagonal pyramids obliquely truncated. Its specific gravity is 1,920.

Its taffe is sharp, bitterish, and cooling.

It is foluble in feven times its weight of water at the temperature of 60°, and in nearly its own weight of boiling water †.

According to Bergman, it is composed of 31 parts of acid, 61 of potals, and 8 of water; but this proportion of acid is undoubtedly too small. According to Mr Kirwan, it is composed of 41,2 of acid, 46,15 of alkali, and 12,65 of water t. Mineral,

It is not altered by exposure to the air.

When exposed to a ftrong heat, it melts; and congeals by cooling into an opake mass, which has been called mineral crystal. If the heat be continued, the acid is gradually decomposed and driven off. When the folution of nitre is exposed to a boiling heat, part of the falt is evaporated along with the water, as Wallerius, Kirwan, and Lavoisier, observed successively. When nitre is exposed to heat along with many combustible fubstances, its acid is decomposed; the combustible seizes the oxygen, and at the same time a lively white slame appears, attended with a decrepitation: this is called the detonation of nitre.

Nitre mixed with charcoal and fulphur in proper

proportions forms gunpowder.

Nitre is decomposed by compound affinities by

Acetite of barytes. No phenomenon has excited the attention of chemi-Reproduccal philosophers more than the continual reproduction tion of a of nitre in certain places after it had been extracted from tre. them. Prodigious quantities of this falt are necessary for the purpoles of war; and as Nature has not laid up great magazines of it as she has of some other salts, this annual reproduction is the only fource from which it can be procured. It became, therefore, of the utmost consequence, if possible, to discover the means which Nature employed in forming it, in order to enable us to imitate her processes by art, or at least to accelerate and facilitate them at pleasure. Numerous attempts accordingly have been made to explain and to imitate these processes.

Stahl, fetting out on the principle that there is only one acid in nature, supposed that nitric acid is merely fulphuric acid combined with phlogiston; and that this combination is produced by putrefaction: he affirmed accordingly, that nitre is composed by uniting together potafs, fulphuric acid, and phlogiston. But this opinion, which was merely supported by very far-fetched analogies, could not stand the test of a rigorous examination.

Lemery the Younger accordingly advanced another: affirming, that all the nitre obtained exists previously in animals and vegetables, and that it is formed in these substances by the processes of vegetation and animalization. But it was foon discovered that nitre exists, and is actually formed, in many places where no animal nor vegetable substance had been decompofed; and confequently this theory was as untenable as the former. So far indeed is it from being true that nitre is formed alone by these processes, that the quantity of nitre in plants has been found to depend entirely on the foil in which they grow *.

At

667 Mitre.

At last by the numerous experiments of several French philosophers, particularly by those of Thouvenel, it was discovered that nothing else is necessary for the production of nitre but a basis of lime, heat, and an open, but not too free communication with dry atmospheric air. When these circumstances combine, the acid is first formed, and afterwards the alkali makes its appearance. How the air furnishes materials for this production is eafily explained, now that the component parts of the nitric acid are known to be oxygen and azot. But how lime contributes to their union it is not so easy to fee. It is a disposing affinity, which, like most others referred to that fingular class, our present knowledge of the nature of affinity does not enable us to explain. The appearance of the potass is equally extraordinary. If any thing can give countenance to the hypothesis, that potass is composed of lime and azot, it is this fingular fact.

2. Nitrat of foda. This falt was called formerly cu-

It forms rhomboidal cryftals. Its specific gravity is 1,870.

It has a cool sharp taste, and is somewhat more bit-It is foluble in about three parts of water at the tem-

perature of 60°, and is fearcely more foluble in boiling

It is composed, according to Bergman, of 43 parts of acid, 32 of foda, and 25 of water. From an experiment formerly described, Mr Kirwan concludes, that it contains 57,65 of acid, and 42,35 of alkali; but perhaps the proportion of acid may be somewhat over-rated, as no direct proof has been brought that the falt contains no water.

When exposed to the air it rather attracts moisture. Its phenomena in the fire are the same with those of

nitre, only it does not melt fo eafily.

It is decomposed by compound affinity by the fol-

lowing falts: Sulphat of barytes, potafs, - alumina, Muriat of barytes, potafs,

Muriat of ammonia, Acetite of barytes, ____ potals, Carbonat of barytes, potals.

- lime, 3. Nitrat of ammonia. This falt crystallizes with difficulty into regular needles. It was formerly called nitrum semivolatile, and nitrum flammans.

It has a sharp, acrid, somewhat urinous taste.

It is foluble in about half its weight of boiling wa-

It is composed of 58 parts of acid, about 26 of al-

rwan. kali, and 16 of water *

When exposed to the air it deliquesces.

When exposed to heat, it first undergoes the watery fusion, afterwards detonates, and is completely decomposed. Berthollet has shewn, that this phenomenon is owing to the hydrogen of the alkali entering into combination with the oxygen of the acid, and forming water, while the acid flies off in a gaseous form.

By compound affinity it is decomposed by the follow-

ing fubstances:

Acetite of barytes, Sulphat of barytes, - potals, potafs, foda alumina,

-	-	
Acetite of	lime,	Muriat of lime,
	magnefia,	magnelia,
-		alumina,
Muriat of	barytes,	Carbonat of barytes,
-		potals,
-		foda.
% T* C	1	This falt may be formed into xx:

4. Nitrat of barytes. This last may be hexagonal crystals, but it requires great address to pro-barytes. duce them.

It attracts moisture from the atmosphere.

Heat decomposes it, and leaves pure barytes. The decomposition of this salt by heat is the most convenient method of procuring pure barytes yet known. It was first proposed by Mr Vauquelin.

By compound affinity it is decomposed by Alkaline carbonats,

Oxalat of ammonia *. 5. Nitrat of lime. This falt forms by crystallization Nitrat of fix-fided prisms, terminated by dehedral pyramids, but lime. more commonly finall regular octahedral needles.

It has a sharp bitterish taste.

It is foluble in two parts of cold water, and in its own weight of boiling water.

Boiling alcohol diffolves its own weight of it +. According to Bergman, it is composed of 43 parts of acid, 32 of lime, and 25 of water. Kirwan has found, that 100 parts of lime require for faturation 180

215.

8. Nitrat of ammonia and magnefia. This triple falt was discovered by Mr Foureroy. Into a faturated foand magne-Intion of nitrat of magnefia, containing 73 grains of magnefia, he poured ammonia as long as any precipitate could be obtained. Twenty-one grains of magneha were precipitated, 52 grains remained combined with the acid and the ammonia. He found that 52 grains of magnefia produced, when faturated with nitric acid, 288 grains of nitrat; and that the quantity of nitric acid necessary to saturate 21 grains of magnesia, when faturated with ammonia, produced 84 grains of nitrat of ammonia. He concludes, therefore, though the data are not quite satisfactory; that the triple salt is composed of 288 grains of nitrat of magnesia, and 84 of nitrat of ammonia *.

9. Nitrat of alumina. This feems to have been first attended to by Baumé.

Its crystals are pyramidal. It has a very astringent taste. It is soluble in water, and deliquesces in the

10. Nitrat of jargonia. This falt may be eafily formed by pouring nitric acid on newly precipitated

jargonia.

It always contains an excess of acid. By evaporation a yellowish transparent matter is obtained, exceedingly tenacious and viscid, and which dries with difficulty. It has an aftringent tafte, and leaves on the tongue a viscid matter, owing to its being decomposed by the faliva. It is only very fparingly foluble in water; the greatest part remains under the form of gelatinous and transparent flakes. Like all the other falts into which jargonia enters, it is decomposed by heat. It is decomposed also by sulphuric acid, which occasions a white precipitate, foluble in excess of acid; by carbonat of ammonia, which produces a precipitate foluble by adding more carbonat; and by an infusion of nut galls in alcohol, which produces a white precipitate, foluble in an excess of the infusion; unless the jargonia contains iron; in which case the precipitate is a greyish blue, and part of it remains infolnble, giving the liquor a blue colour. This liquor, mixed with carbonat of ammonia, produces a matter purple by transmitted light, but violet by reflected light. Gallic acid also precipitates nitrat of jargonia of a greyish blue, but the colour is not fo fine. Most of the other vegetable acids decompose this falt, and form combinations infoluble in

& Vauquelin, water + Ann. de Chim xxii. 190. Nitrat of

679

Nitrat of

11. Nitrat of iron. The green oxyd of iron decompoles, but does not combine with nitric acid. The brown oxyd forms with it a red or brown folintion, which by evaporation may be reduced to a jelly, but will not crystallize.

12. Nitrat of zinc. The oxyd of zinc combines with nitric acid, and forms with it a falt which cryftallizes in compressed and striated tetrahedral prisms, termiseted by four fided pyramids.

Its folution is exceedingly caustic. When placed Nitrate on burning coals it melts and detonates as it dries. It can scarcely be dried without being in some measure de-

It deliquesces in the air *. * Fourcroy. 13. Nitrat of manganele. This falt, composed of Nitrat of Nitrat of oxyd of manganese and nitric acid, was first examined manganese by Scheele. Its crystals are fmall and shining, of a very bitter taste, and soluble in water +.

14. Nitrat of cobalt. It is of a pale red colour, and Manganga crystallizes in needles. It deliquesces when exposed to Nitrat of the air. Heat decomposes it. When nickel is present, cobalt, this falt affumes a green colour.

15. Nitrat of nickel. Its crystals are of a green co Of nickel, lour, and in the form of rhomboidal cubes. They are deliquescent, and are gradually decomposed when expofed to the air, the acid leaving them ‡.

16. Nitrat of lead. Nitric acid combines with the ii. 20%, white oxyd of lead. The crystals of this falt are of a Of lead, t Bergman white colour; their form an irregular octagon, or rather truncated hexahedral pyramid. When exposed to heat it decrepitates, and melts with a yellowish flame. By compound affinity it is decomposed by

Muriat of potafs, - foda, - ammonia, Carbonat of foda f.

17. Nitrat of tin. Tin is converted into an acid by nitric acid: it is not probable, therefore, that any per- Of tin, manent nitrat of tin can be formed.

18. Nitrat of copper. This falt appears to have been Of copper, first obtained by Macquer.

Its form, when properly crystallized, is an oblong parallelogram. It is of a fine blue colour. It is exceedingly caustic. It melts at 77° ¶.

It is deliquescent in a moist air, but in a dry place is covered with a green efflorescence. It is very soluble in water. Heat decomposes it.

19. Nitrat of bismuth. This falt crystallizes in va-Ofbismuth. rious forms. Fourcroy obtained it in flattened rhomboids. It effloresces in the air. Water decomposes it. It detonates in the fire.

20. Nitrat of antimony. Little is known concern- Oranimoing this falt, except that it is very deliquefcent, and is ny, decomposed by heat.

21. Nitrat of arsenic. With white oxyd of arsenic Of artenic nitric acid forms a falt which cryftallizes. It is very deliquescent. It does not detonate.

22. Nitrat of mercury. This falt may be formed by Of mercudiffolving mercury in nitric acid. It cryftallizes in the ry, cold in regular flat 14-fided figures; but their form differs according to the manner in which the crystallization has been performed.

It is foluble in water.

This falt is exceedingly caustic. It detonates on coals. When heated in a crncible it melts, and is decomposed. The oxyd attracts oxygen from the acid, which flies off in the form of nitrous gas, and red oxyd of mercury remains behind.

It is flowly decomposed also in the air. It is decomposed by compound affinity by

Sulphat of copper, and a great many other fulphate, l'hosphat of soda,

23. Nitrat of ammonia and mercury. This triple Of animofalt may be formed by pouring ammonia into a folution min and of mercury.

Ann. de

Chim. vi.

29. + Bullen,

† Morveau. & Bergman.

| Morveau,

of nitrat of mercury. If only enough of ammonia to faturate the acid be used, the triple salt precipitates in the form of a white powder; but with an excels of ammonia it remains diffolved, and forms by evaporation very bright polyhedral crystals.

It has a very tharp tafte. It is foluble in 1200 parts of water at the temperature of 55°. Hot water feparates a little ammonia, which renders it still more insoluble. It turns vegetable blues green. Muriatic acid

According to Fourcroy's analysis, it is composed of 68,20 parts of oxyd of mercury, 16 of ammonia, and 15,80 of nitric acid and water.

When distilled it yields ammonia, azotic gas, oxygen

y, gas, yellow oxyd of mercury, and pure mercury *.

24. Nitrat of filver. This falt may be formed by

diffolving filver in nitric acid.

It forms flat transparent crystals composed of needles. It is exceedingly caustic. When melted it forms a grey mass called lapis infernalis, from its great corrosiveness.

It is very foluble in water. It is not altered by ex-

posure to the air. Light decomposes it.

By compound affinity it is decomposed by

The fulphats, The muriats.

25. Nitrat of uranium. This falt was first formed by Klaproth. Its crystals are hexagonal plates of a greenish yellow colour. The largest were 3ths of an inch in length and th in breadth +.

26. Nitrat of titanium. It is capable of crystallizing. 27. Nitrat of tellurium. The folution of tellurium in nitric acid is transparent and colourless. When concentrated, it produces in time small white light crystals in the form of needles, which exhibit a dendritic agm gregation ‡.

SECT. IV. Of Nitrites.

THE falts which the nitrous acid forms with alkalies, earths, and metallic oxyds, are denominated nitrites. Very few of them have been examined; we shall not therefore attempt a description of them.

SECT. V. Of Muriats.

SALTS into which the muriatic acid enters are called

muriats. 1. Muriat of potass. 'This falt was formerly called febrifuge or digestive falt of Sylvius, and regenerated sea falt. Its cryftals are cubes, but rather irregular.

It has a disagreeable bitter tafte. Its specific gravi-

in. ty is 1,836 s.

2 tb,

It is foluble in three times its weight of water at the temperature of 60°, and in double its weight of boiling an. water ¶.

It is composed, according to Bergman, of 31 parts of acid, 61 of potals, and 8 of water. Kirwan has found it to contain 36 of acid, 46 of alkali, and 18 of

It fuffers little alteration from exposure to the air. When exposed to heat, it first decrepitates, then melts, and at last is volatilized, but without decomposition.
The following falts decompose it by compound affinity:

-	ammonia,	-	
-			
Nitrat of			lead.
	lime,		
SUPPL. VOL	I. Part I.		

2. Muriat of soda, common or sea salt. This salt Muriats. has been known, and in common use, from the earliest ages. It is fometimes called also fal gem.

Its crystals are cubes, but they often assume other soda. forms. Its specific gravity is 2,120 *.

Its taste is universally known, and is what is strictly

fpeaking denominated falt.

It is foluble in 2 14 times its weight of water at the temperature of 60°, and in 213 its weight of boiling

According to Bergman, it is composed of 52 parts of acid, 42 of alkali, and 6 of water. According to the late experiments of Mr Kirwan, of 40 parts of acid, 35 of alkali, and 25 of water.

It is not affected by exposure to the air. It ought to be observed, however, that the muriat of soda in common use contains, besides other impurities, a quantity of niuriat of magnefia, which renders it deliquescent.

When heated it decrepitates. Heat volatilizes, but

does not decompose it.

The following falts decompose it by compound affi- * Fuchs, Sulphat of ammonia, Nitrat of filver o, alumina, Acetite of barytes, - potass *, Pyrolignite of barytes ||, _____ iron †, ____ lead ||, Nitrat of ammonia, Carbonat of potass (a), Alum (b), --- magnefia, ____ alumina, Red oxyd of lead (c). _____ lead ‡,

That the red oxyd of lead decomposes this falt is a 109. well known fact, and it has been confidered as contrary (a) Bergman to the laws of affinity. Mr Haffenfratz endeavoured to (b) Crell, account for it by supposing that the oxyd is com- Chim. xxvi. bined with carbonic acid, and that therefore it is a case 297. of compound affinity. Mr Curaudau has proved that (c) Scheele. carbonic acid, instead of promoting, impedes the decomposition; and that, in fact, carbonat of lead is inca-composed pable of decomposing muriat of soda. He concludes, by red oxyd therefore, that the phenomenon cannot be accounted of lead. for by the commonly received laws of affinity*. We * Ann. de cannot, however, think, that the phenomenon is fo Chim. xiv. unaccountable as Mr Curaudau supposes; for muriatic acid is capable of decompoling the red oxyd of lead, of combining with part of its oxygen, and of being converted into oxy-muriatic acid. Now if oxy-muriatic and nitro-muriatic acids be merely the same substance in a different form, as there is the strongest reason for suppoling, the white oxyd of lead has a stronger affinity for it than foda has, and ought therefore to decompose it.

3. Muriat of ammonia, or sel ammoniac. This salt Muriat of was known to the ancients, and was called by them falammonia. ammoniac, because it was found in great quantities near

the temple of Jupiter Ammon in Africa*.

** **Fliny,
It assumes the form of plumose crystals. The indication axis. vidual crystals are long hexahedral pyramids. Its spe-Sal Anmocific gravity is 1,420 +. niac, Encyc.

It has an acrid, poignant, urinous taste.

It disfolves in about three times its weight of water at the temperature of 60°, and in a much smaller quantity of boiling water.

It is composed, according to Kirwan, of 35 parts of acid, 30 of alkali, and 45 of water ‡.

In its common form (which is an opaque mass) it is in 34. not affected by the air, but its crystals are liable to de-

Muriate.

Heat volatilizes without decomposing it. The following falts decompose it by compound affi-

Sulphat of alumina, Acetite of magnefia, Nitrat of foda, --- alumina, --- lead, - lead, Acetite of barytes, Carbonat of barytes, - potafs, ---- potafs, --- magnefia (Y) - foda, - lime,

When this falt is fublimed with gold leaf, there is found in the neck of the retort an ameth, it coloured matter, bordering on purple, soluble in water, and forming a purple folution. When filtered there remains behind a purple powder. This falt feems from this to be capable of oxydating gold *.

4. Muriat of barytes. This falt was first described

* Storr, Crell's New Differences, by Bergman, but it has been most particularly attended

699 Muriat of

barytes,

&c. Part ii to by Dr Crawford. It affords oblong square crystals. It has an unpleasant astringent taste.

It is not very soluble in water. It is soluble in alcohol.

It is not altered by exposure to the air, nor does heat in all probability decompose it.

Dr Crawford wrote a treatise on it in 1790, in which he recommended its use internally for scrofulous complaints. Care ought to be taken not to give it in too large quantities, as, like the other compounds of barytes, it is poisonous.

The following falts decompose it by compound affi-

nity (z):.

Sulphat of foda Nitrat of lime, ammonia, - ammonia, - magnefia, - magnefia, alumina, - alumina, Nitrat of foda, Phosphat of lime *. 5. Muriat of ammonia and barytes. This triple falt

lime,

6. Muriat of lime. This falt was formerly called 701

fixed ammoniae, because it was commonly obtained by Muriat of decomposing sal ammoniac by means of lime. Its crystals are four sided striated prisms, terminated

by a very sharp pyramid; but it is not easily crystallized.

Its tafte is very bitter.

It is foluble in about 12 parts of cold water, and in less than its own weight of boiling water. Alcohol dissolves its own weight of it.

According to Bergman, it is composed of 31 parts of acid, 44 of lime, and 25 of water. According to Kirwan, 100 parts of lime require for faturation 86 parts of muriatic acid.

It very speedily deliquesces when exposed to the air. Murida By heat it melts into a very hard vitreform sub-

Nitrat of ammonia, Carbonat

(x) Only at the common temperature. At a high temperature carbonat of ammonia decomposes muriat of magnesia. See Westrum, Ann. de Chim. ii. 118.

(z) Bergman affirmed, that this falt decomposed all the fulphats, and proposed it therefore as a certain means of discovering the presence of sulphuric acid, however combined in any solution; for the sulphat of barytes is almost entirely insoluble in water. But Mr Piffis has observed, that it does not decompose sulphat of lime nor of potass. See Ann. de Chim. xv. 317.

Carbonat of barytes, Carbonat of foda, ammonia(Y)

9. Muriat of ammonia and magnefia. This triple falt was first mentioned, we believe, by Bergman. It may be formed by pouring ammonia into a solution of muriat of magnesia. Part of the magnesia is precipitated, but great part of it remains dissolved, and combined with the acid and the ammonia. This triple salt is composed, according to Fourcroy, of 73 parts of muriat of magnesia and 27 of muriat of ammonia †.

difficulty. It has an aftringent tafte. Its folution is gelatinous, and cannot be filtrated without much dilution in water. It is deliquefcent. When evaporated to dryness, it forms a gummy mass: in a strong heat it

is decomposed.

The following falts decompose it by compound affi-

nity:

by pouring muriatic acid on newly precipitated jargonia. It is colourless; its taste is very astringent: by evaporation it furnishes small transparent crystals in needles, which lose their transparence in the air. Muriat of jargonia is very soluble in water and in alcohol; to the slame of which it does not communicate any particular colour. Heat decomposes it; and it is decomposed likewise by the saliva when taken into the mouth.

When muriat of jargonia contains a little filica, it forms cubic crystals without confidence, and refembling a jelly. These crystals, when exposed to the air, gradually lose their transparency, and diminish in volume, and there are formed in the middle of the salt

white filky needle-shaped crystals.

Muriat of jargonia is decomposed by sulphuric acid; part of the sulphat precipitates, and part remains dissolved in the muriatic acid. When this acid is driven off by heat, the remainder of the sulphat is gradually deposited: if the evaporation be stopped before the mass be reduced to dryness, it forms a kind of jelly when cold. It is also decomposed by the phosphoric, citric, tartarous, oxalic and saccholactic acids, which form with jargonia insoluble compounds that precipitate in white slakes.

The gallic acid poured into muriat of jargonia produces a white precipitate; but a green, bordering on grey, if the jargonia contain iron; and this last precipitate becomes, when dry, of a bright black colour, and refembles China ink. The liquid preserves a greenish colour; new portions of gallic acid produce no farther precipitation; but carbonat of ammonia separates in great abundance a slaky matter of a purplish colour, not unlike that of the leys of wine. From these experiments it follows, that gallic acid has a greater affinity for jargonia than muriatic acid has; and that the gallats of jargonia and iron are soluble in muriatic acid.

Carbonat of potafs decomposes muriat of jargonia,

and part of the carbonic acid combines with the earth, Muriats. and renders it eafily foluble in acids though dried.

Carbonat of ammonia occasions a precipitate, which is mostly dissolved by adding more carbonat.

Pruffiat of mercury produces an abundant precipitate, which is foluble in muriatic acid; and which con-

fequently is not muriat of mercury.

A plate of zinc, introduced into a folution of muriat of jargonia, occasions a slight effervescence; the liquor becomes milky, and in a few days becomes a white semitransparent jelly.

Alumina decomposes muriat of jargonia with the affishance of a slight heat; the alumina dissolves, the liquor becomes milky, and assumes the form of a jelly. When the muriat contains iron, it remains in the solution, and the precipitated jargonia is quite pure. Here, then, is a method of freeing jargonia from iron *. *Vauquelin,*

T2. Muriat of iron.—Muriatic acid forms with the Chim. xxii. green oxyd of iron a falt which crystallizes in flat 201. needles. When exposed to the air, they deliquesce, 707 and the green oxyd attracts oxygen, and is gradually Muriat of converted into a brown oxyd. Heat decomposes this iron, falt.

13. Muriat of zinc. This falt, procured by diffol-Muriat of ving zinc or its oxyd in muriatic acid, does not cryftal-zinc, lize. Its folution is colourles. When heated, it becomes of a blackish brown By distillation, a part of the acid is separated, and muriat of zinc remains behind of a milk white colour, solid, and formed of small radiated needles. It attracts mostlure in the air.

14. Muriat of manganese. Muriatic acid diffolves Muriat of the white oxyd of manganese. Its solution affords by parganese, evaporation angular shining crystals †: They are deli-† Scheele on quescent and soluble in alcohol ‡.

15. Muriat of cobalt. The folution of oxyd of co- Kirwan's balt in muriatic acid is of a pale red, except it be con-37. taminated with nickel or iron, when it is greenish. It 710 crystallizes in small needles, which are very deliquescent. Cobalt, Heat decomposes it.

16. Muriat of nickel. This falt is deliquescent, and Nickel,

lofes its acid when exposed to the air ¶.

17. Muriat of lead. Muriatic acid combines withii 208.

oxyd of lead easily enough: but this salt is more readily procured by pouring muriatic acid into a solution of nitrat of lead; the muriat immediately precipitates in the form of a white powder. It is soluble in 30 times its weight of boiling water; and the solution yields by evaporation small, slender, brilliant needles in bundles.

It is somewhat deliquescent. When exposed to heat, it melts into a brown mais, formerly called corneous

lead.

It is decomposed by compound affinity by Sulphat of filver*,

Carbonat of foda.

18. Muriat of tin. This falt may be formed by diffolving tin in hot muriatic acid. By evaporation, it affords needle shaped crystals, which are deliquescent.

This falt has a strong affinity for oxygen. It decomposes oxy-muriatic, nitric, sulphurous, arsenic, molybdic and tungstic acids, the red oxyd of mercury, black oxyd of manganese, oxyd of antimony, zinc, fil-

muriat of tin. It even absorbs oxygen when exposed * Pelletier, to the air *. These compositions are doubtless produced by disposing affinity.
19. Muriat of copper. This falt may be formed by

diffolving copper or its oxyd in muriatic acid. Muriat of

Its crystals are prismatic. It is of a beautiful grass green colour. It has a very aftringent and caustic taste. It deliquesces when exposed to the air. A moderate heat is sufficient to melt it; and when cooled it congeals into a mass. It requires a strong heat to volatilize it.

It is decomposed by nitrat of filver +.

715 Muriat of 20. Muriat of bilmuth. This falt crystallizes with difficulty. By fublimation it forms a foft fufible fubbismuth, stance, formerly called butter of bifmuth. 716

21. Muriat of antimony. This falt is found native. It crystallizes in prisms. When heated, it evaporates. This falt is found native. Antimony,

22. Muriat of arfenic. This falt crystallizes; it is very volatile, and not very foluble, in water ‡.

\$ Bergman, ii 293. 23. Muriat of mercury. This falt may be prepared 718

by pouring diluted muriatic acid into a diluted folution of nitrat of mercury: the muriat of mercury is immediately precipitated in the form of a white powder. Common salt may be used instead of muriatic acid. This falt was formerly called white mercurial precipitate and calomel.

It crystallizes; but the form of the crystals, which are very small, has not been determined.

It has little taste. It is almost insoluble in water.

It is used as a medicine.

It is decomposed by sulphat of ammonia *.

24. Muriat of ammonia and mercury. This triple falt was first discovered by Fourcroy. It may be formed by pouring ammonia into a folution of corrofive muriat of mercury. It has the appearance of a white powder. Its taste is at first earthy, afterwards metallic. It is nearly infoluble in water. According to Fourcroy's analysis, it is composed of 81 parts of oxyd of mercury, 16 of muriatic acid, and 3 of ammonia.

Heat decomposes it; producing ammonia, azotic gas,

and muriat of mercury.

Sulphuric, nitric, and muriatic acids decompose it +. 25. Muriat of filver. This falt may be formed by diffolving oxyd of filver in muriatic acid, or, which is better, by pouring muriatic acid into nitrat of filver; muriat of filver immediately precipitates. It is very little foluble in water; according to Monnet, one part of it requires 3072 parts of water.

When exposed to a small heat, it melts into a grey semitransparent mass, not unlike horn; hence it was formerly called luna cornea. A long continued heat decomposes it. This falt is very caustic: it is employed as an ef-

charotic under the name of lunar caustic. 721 Muriat of

26. Muriat of titanium has been formed by Mr Klaproth.

SECT. VI. Of Oxy-muriats.

THOSE falts, into which the oxy-muriatic acid enters as an ingredient, are called oxy-muriats. As we confider the nitro-muriatic acid to be precisely the same with the oxy-muriatic, its combinations of course must receive the fame name.

1. Oxy-muriat of potals. This fingular falt was dif- Oxy covered by Mr Berthollet in 1786. It may be formed by faturating a folution of potals with oxy muriatic acid gas. By evaporating this folution in the dark, 0xy-1 common muriat of potals is first obtained: When it is reat of feparated, and the liquor allowed to cool, oxy-muriat afs, of potals crystallizes.

Its crystals are rhomboids, of a filvery brilliancy. It has an infipid cooling tafte, refembling that of nitre. It is foluble in 17 parts of water at the temperature of 60, and in 21 parts of boiling water ¶. It does not ¶ Hoy, deliquesce in the air; but light converts it into com- Jeurna mon muriat by separating oxygen. When heated, it 292.

melts, and gives out oxygen gas; and this is the best method hitherto discovered of obtaining that gas in a state of purity. According to Mr Hoyle, it contains about half its weight of concrete oxygen *.

When mixed with charcoal, iron, and many other combustibles, and heated, it detonates with astonishing violence. This property induced the French chemists to propose it as a substitute for nitre in the preparation of gunpowder. The attempt was made at Effons in 1788; but no sooner had the workmen begun to triturate the mixture of charcoal, fulphur and oxy muriat, than it exploded with violence, and proved fatal to Mr Letors and Mademoilelle Chevraud. The force of this gunpowder when it is prepared is much greater than that of the common fort of powder; but the danger of preparing it, and even of using it after it is prepared, is so great, that it can hardly ever be substituted with advantage for common gunpowder.

Fourcroy and Vauquelin afcertained by experiment, that this falt exploded when triturated with fulphur, charcoal, antimony, arfenic, cinnabar, fugar, gums, oils, alcohol, ether, and fulphuret of iron. When these substances were mixed, and struck with a hammer, the explofion took place. The theory of these explosions was first pointed out by Mr Berthollet. The oxygen of the oxy-muriatic acid combines with the combuftible, and at the same time lets go a quantity of caloric; and trituration or percuffion acts merely by bringing the particles which combine within the sphere of

each others attraction.

2. Oxy-muriat of foda. This falt was discovered at Oxy-muriat the same time by Mr Berthollet. Its properties are riat of h the same with the last, except that it is too deliquescent to be used.

3. Oxy-muriat of ammonia. This combination is impossible. The oxy-muriatic acid and ammonia de-

compose each other.

f barytes.
- lime.
- magnefia.

fefs the property of detonating with combustibles, and magnette of being reduced by that means to the state of common muriats. Mr Tennant has lately proposed the oxymuriat of lime as a substitute for the other substances formerly used in the new mode of bleaching; particularly for bleaching printed cottons: And, as far as we can learn, it answers the purpose remarkably well (z).

7. Oxy muriat of mercury. This falt was formerly Oxy man called corresive sublimate, and afterwards corresive muriat riat of m of cury,

(z) We have been informed, that this falt had been used by bleachers in Scotland some years before Mr Tennant proposed it.

x) 14. of mercury.

its composition.

This falt was mentioned by Rhafes in the 10th century; and it feems to have been known in the east at a much earlier period (A). The methods of preparing it used by the older chemists were numerous, complicated, and generally concealed as fecrets. We shall not attempt, therefore, to give any account of them; and the methods used by later chemists have been described at confiderable length in the article CHEMISTRY (Encycl. nº 815)

It may be prepared by diffolving mercury in a fufficient quantity of oxy-muriatic acid, or by diffolving red

oxyd of mercury in common muriatic acid.

When carefully crystallized, this falt affumes the form of cubes or oblique parallelopipeds, or rather quadrangular prisms, with fides alternately narrower, and erminated by two inclined planes meeting together,

It has an exceedingly disagreeable metallic taste. It is foluble in 19 times its weight of water at the Iman. temperature of 50° 1. Boiling water, according to Macquer, diffolves halt its weight of it. Alcohol, at the temperature of 70°, diffolves 3ths of its weight of this

It does not attract moisture from the air.

It is foluble in fulphuric, nitric, and muriatic acids.

When triturated with 3ths of its weight of mercury and a little water, and then fublimed, it forms a white infiped falt, called formerly calomel or fweet mercury: This, as Scheele has proved, is precifely the fame with

common muriat of mercury.

The theory of these two preparations is now pretty obvious. The experiments of Adet and Pelletier have shewn, that oxy-muriatic acid may be obtained from corrosive muriat of mercury \mathbb{q}. We may conclude, therefore, with confidence, that the falt is an oxy-muriat. It cannot be prepared by means of common muriatic acid, except with red oxyd of mercury, or fome other substance from which it may absorb oxygen. When pure mercury is added to oxy-muriat, it feizes the oxygen from the oxy muriat, and the whole is converted into common muriat.

It is decomposed by

(-mue

Tartar,

Most metals. 8. Oxy muriat of tin. When an amalgam of tin is of tin, triturated with its own weight of corrolive naviat of mercury, and the mixture is diffilled in a glass retort by means of a very gentle heat, there paffes over a thick white smoke, which condenses into a colourless liquor that emits copious fumes, and has been called, in consequence, fmoking liquor of Libavius. This liquor was examined by Mr Adet. He found, that when about Id part of water was added to this liquor, it ceased to fume, and affumed a crystalline form; that then it might be even made red hot without fubliming. It therefore owes its volatility to want of water, or rather to a ftrong attraction for water. He found that this substance was capable of disfolving, and therefore of oxydating more tin, without the emission of any hydrogen, and confequently without the decomposition of

Berthollet first pointed out the nature of water; he concluded from this, that it was composed Phosphats. of oxy-muriatic acid and tin §. This has been composed on the concluded from this has been composed to the concluded from this has been composed from the concluded from this has been composed from the concluded fr pletely proved by Mr Pelletier, who found, that when Chim. i. 3. oxyd of tin was combined with oxy muriatic acid, it formed a compound precifely the fame with the smoking liquor of Libavius *.

ng liquor of Libavius *.
This falt may be prepared, as Pelletier has proved, 225. by diffolving tin in muriatic acid, and then faturating it

with oxy muriatic acid gas.

It is used in dyeing. 9. Oxy-muriat of iron. This falt is deliquescent; Oxy mucolourless; of a pure bitter tafte, without any of the riat of iron. fweet aftringency of the common fals of iron ||.

Few of the other oxy muriats have been hitherto ex- Manchester amined with attention: Many of the metals, indeed, p. 1. have been diffolved in aqua regia; but in most of these folutions the falt produced is a common muriat. The nitric acid supplies oxygen, and the muriatic acid disfolves the oxyd.

SECT. VII. Of Phosphats.

THOSE falts, into which phosphoric acid enters as an ingredient, are called phosphats. This class of falts was first discovered by Margraf.

1. Phosphat of potass. This salt crystallizes in short Phosphat tetrahædral prisms, terminated by quadrangular pyra of potass,

It is very foluble in cold water, and still more so in

It decrepitates on ignited coals like common falt. When a very strong heat is applied, it melts into an opaque vitreous mass, still soluble in water.

The following falts decompose it by compound affi-

Muriat of mercury, Sulphat of lime, Acetite of lead. Nitrat of mercury,

2. Phosphat of seda - Dr Pearson, who first formed Phosphat this falt, gives the following process for preparing it: of soda,

Diffolve in a long-necked matrass 1400 grains of crystallized carbonat of soda in 2100 grains of water at the temperature of 150°. Add gradually 500 grains of phosphoric acid of the specific gravity 1,85. Boil the liquor for fome minutes; and while it is boiling hot, filtrate it, and pour it into a shallow vessel. Let it remain in a cool place, and crystals will continue to form for feveral days. From the above quantities of materials he has obtained from 1450 to 1550 grains of crystals.

Its crystals are rhomboidal prifms, of which the acute angles are 60°, and the obtuse angles 120°, terminated by a three-fided pyramid.

Its tafte is almost the same with that of common falt. It is foluble in water. When exposed to the zir it effloresces.

This falt has been introduced into medicine as a purgative, and on account of its pleasant taste has of late been much used. It is usually taken in broth. which it is employed to feafon inflead of common falt.

Hellot remarked a particular falt in urine, different from those that had usually been observed, in 1737. Haupt described it in 1740 under the name of fal mi-

(A) If we listen to Junker, the ancients applied the name mercurium to this falt; mercury they called argentum vivum.

Phosphets rabile perlatum, or wonderful perlated falt. It was called perlated from the grey, opaque, pearl-like colour which it affurned when melted by the blow pipe. Mar graf described it in 1745, and found it would not yield phosphorus when treated with charcoal, as the other falts of urine did. Rouelle the Younger analysed it in 1776, and concluded from his experiments that it was 1776, and concluded from his experiments that it was 15. Phosphat of antimony and line.—Dr Pearson of una compound of phosphoric acid and soda; but Mr has discovered, that the well-known medicine called 722 Prouft, being unable to obtain phosphorus from it, concluded, that it did not contain phosphoric acid, but another acid analogous to the boracic. To this substance, which Mr Proust actually obtained, Bergman gave the name of perlated acid, and Morveau afterwards called it ouretic acid. But Mr Klaproth foon afterwards analysed it, and proved that it confisted of soda fuperfaturated with phosphoric acid. Scheele soon after made the same discovery. This acid of Mr. Proust, then, is merely phosphat of foda combined with phofphoric acid, or acidulous phosphat of soda. 3. Phosphat of ammonia - This falt forms oblong-

Phosphat of ammo-

pointed crystals, or, as Mr Lavoisier affirms, crystals refembling those of alum.

It is foluble in water. Heat evaporates it so easily, that it is difficult to obtain it in crystals except by adding an excess of alkali.

Microcosmic salt, or salt of urine, is merely a mixture

of these two last described salts.

731 Of barytes, 4. Phosphat of barytes. - This falt is infoluble in + Morveau. water +.

5. Phosphat of lime - This falt is tasteless, and almost perfectly insoluble in water. It forms the basis of bones, and is therefore often called earth of bones. Wenzel observed it crystallize when held in solution by +Delkeskamp phosphoric acid.

It is decomposed by fulphat of ammonia *. Ann. de Chim. vi. Carbonat of potass+, 37. + Bergman. foda ‡.

6. Phosphat of strontites. - This falt was first formed ‡ Id. by Dr Hope. It is a white powder, foluble in 1920 Of firon-

parts of boiling water *. tites.

7. Phosphat of magnefia. This falt does not crystallize except with excess of acid, and then the cry-Trans. Edin. iv. stals are very small. Somewhat longer crystals may be formed by dropping phosphoric acid into acetite of magnesia. It most commonly forms by evaporation a gum-Of magnemy mass. It is soluble in alcohol +.

It is infoluble in nitric acid. It melts by a strong

† Bergman, ii. 390. * Wenzel. heat into a porcelain-like fubstance *.

8. Phosphat of alumina. - This is a faline powder, insoluble in water. Diffolved in phosphoric acid, it yields a gritty powder, and a gummy folution, which by heat is converted into a transparent glass.

9. Phosphat of iron. This falt is merely a dry adhefive mass, infoluble in water, but soluble in acids. With excess of acid, it forms crystals which do not deliquesce, and by heat are converted into a garnet-co-

7 Id. loured glass . Of zinc,

10. Phosphat of zinc .- It does not crystallize, but when evaporated becomes a gummy mass, which may be melted into a transparent glass t.

Of manga-11. Phosphat of manganete.—The folution of the oxyd of manganese in phosphoric acid is reddish, but becomes white on exposure to the air. Of nickel,

12. Phosphat of nickel. - It is greenish, and does not * Bergman, crystallize *.

13. Phosphat of arfenic. It crystallizes in small Bura grains hardly foluble in water †.

14. Phosphat of uranium.—First formed by Klap-of arts roth. It does not crystallize, but assumes the appearance of yellowish white slakes, difficultly soluble in ii. 290,

Jomes's powder is a triple falt, composed of photphoric James acid, oxyd of antimony, and lime. It is very infoluble power

The remaining phosphats are scarcely known.

SECT. VIII. Of Borats.

THE compounds into which the boracic acid enters are called borats.

Borat of potals.—This falt, formed by combining Borat of racic acid and potals, is very little known. Baron Potals, boracic acid and potass, is very little known. Baron first formed it. Eorat of potals crystallizes, is soluble in water, and may be melted into a vitreous mass, soluble in water.

2. Borat of foda or borax. This falt is brought of foda from the East Indies in an impure state under the name of tinkal. When purified in Europe, it takes the name

of borax.

Its crystals are hexangular prisms, of which two sides are much broader than the remainder, terminated by triangular pyramids. It is of a white colour. Its specific gravity is 1,740.
Its tase is styptic and alkaline.

It is foluble in 18 times its weight of water of the temperature of 60°, and 6 times its weight of boiling

It is composed, according to Bergman, of 17 parts of foda, 39 of acid, and 44 of water.

When exposed to the air, it effloresces slowly and

flightly.

When heated, it fwells, loses about four tenths of its weight, becomes ropy, and then affumes the form of a light, porous, and very friable mass, known by the name of calcined borax; it then melts into a transparent glass, still soluble in water.

By compound affinity it is decomposed by Nitrat of mercury *.

When two pieces of borax are struck together in the dark, a flash of light is emitted +.

Borax has the property of facilitating the fusion of Nicholon great number of hodies. This property a great number of bodies. This property renders it 25. useful in glass making, in affaying ores, and in solder-

Borax turns fyrup of violets green; it appears there-

fore to be supersaturated with alkali.

The real borat of foda, or the falt in which boracic acid and foda faturate each other, has not yet been examined with attention. According to Dr Withering, foda requires twice its weight of boracic acid to fatu-

3 Borat of ammonia.—This falt has been examined of animo only by Mr Fourcroy.

Îts crystals are polyhedral pyramids.

It has a poignant urinous tafte, and turns fyrup of violets green. It dissolves readily enough in water. Fourty, When exposed to the air, it gradually loses its crystal- Chemilty. line form and becomes brown t. Part ii.

4. Boratch. 4.

4. Borat of barytes. - Unknown.

5. Borat of lime. - It is difficultly foluble in water,

and did not crystallize with Beaumé.

6. Borat of strontites .- This falt was first formed by Dr Hope.—It is a white powder, foluble in about 130 parts of boiling water. The folution turns the fyrup din. of violets green *.

7. Borat of magnefia.—It affumes the appearance of fmall irregular crystals. It is foluble in acetous and formie acids. Alcohol decomposes it. It melts easily in

m, the fire without being decomposed ‡.

8. Borat of alumina.—It does not crystallize, and is

fcarcely foluble in water.

9. Borat of iron.—Its crystals are of a yellow colour, but the falt has never been examined with attention.

10. Borat of zinc .- This falt does not appear to be capable of crystallizing. By heat, it melts into a light

green insoluble slag .

11. Borat of cobalt .- When oxyd of cobalt is melted with boracic acid, a bluish grey slag is produced. This, by lixiviation and evaporation, yields crystals of a reddish white colour and ramified form §.

12. Borat of nickel. - A faline fubitance difficultly

Be van. foluble *.

13. Borat of lead .- When boracic acid and red oxyd of lead are melted together, the product is a fine green-

ish yellow, transparent, hard, insoluble glass ‡. 14. Borat of tin. - When equal parts of boracic acid and tin filings are melted together, the product diffolved in water yields by evaporation transparent white

polygonous cryftals.

15. Borat of copper. - When borax is poured into a folution of fulphat of copper, borat of copper is precipitated in the form of a pale light green jelly, which when dried is with great difficulty foluble in water. It eafily 8 man. melts into a dark red vitreous substance *. According to Paim, by long trituration of filings of copper and boracic acid in water, and then digefting the mixture, it diffolves, and crystals may be obtained from it.

16. Borat of bismuth .- A white powder, which

melts into a white transparent permanent glass +.

17. Borat of arfenic. - White oxyd of arienic and boracic acid form a falt foluble in water and crystallizable *.

SECT. IX. Of Fluats.

THOSE falts into which fluoric acid enters are called fluats. They were first formed by Scheele.

1. Fluat of potals. It forms a gelatinous mals al-

most without taste.

It diffolves readily in water. When exposed to the

s cleon fire it melts without any ebulition ‡.

2. Fluat of foda. This falt reiembles exactly the

fluat of potass +.

ites,

3. Fluat of ammonia. It crystallizes in small prisms. It is deliquescent, and is partly decomposed by heat *.

It is decomposed by

Nitrat of mercury, ___ filver, --- lead.

4. Fluat of barytes. A powder which requires a large gman. quantity of water to diffolve it *.

5. Fluat of lime. This falt abounds in nature. It

is known by the name of fluor spar.

It crystallizes most commonly in the form of cubes.

It is ta'teless and nearly insoluble in water.

It is not altered by the air. Its specific gravity is

When exposed to a sudden heat it decrepitates. A very violent heat melts it into a white opaque mass.

When reduced to powder and heated it becomes phofphorescent; but it loses this quality altogether if it be heated red hot.

6. Fluat of strontites. This falt was formed by Dr Hope: but its properties have not been examined.

7. Fluat of magnefia. It is not foluble in water ex-Magnefia, cept there be an excess of acid. In that case, by spontaneous evaporation, it forms hexagonal prisms, terminated by a low pyramid composed of three rhomboidal

These crystals are hardly soluble in water. Alcohol dissolves a small portion of them. Heat does not decompose them +.

8. Fluat of alumina. A faline mass; which is sweetish, clammy, and gelatinous.

9. Fluat of filica. Little is known concerning this fingular combination, except that it can exist in a ga- Silica, feous form, and that it deposites silica in crystals after a

10. Fluat of filica and potass or soda. This triple falt may be formed by pouring fixed alkali into a solution of fluat of filica. It contains an excess of acid. On evaporation it yields a kind of jelly, which when dry separates into gritty particles like fand. luble in 96 parts of hot water. In the fire it readily melts into a white mass. If the heat be continued the acid separates, and there remains a transparent glass, which is foluble in water, and forms a liquor filicum t. \$ Scheele,

11. Fluat of iron. It is incrystallizable; but when Grell's Jour ... evaporated leaves a hard mass. Eng. transf.

12. Fluat of zinc. It resembles that of iron. 13. Fluat of manganese. It may be formed by pour-Metalic ing fluat of ammonia into a folution of oxyd of zinc in fluats. any of the three mineral acids. It crystallizes.

14. Fluat of cobalt. A yellow gelatinous mass. 15. Fluat of nickel. It affords green crystals. 16. Fluat of lead. A sweet tasted powder.

17. Fluat of tin. A nauseous tasted jelly. 18. Fluat of copper. Blue crystals; some of them

oblong, others cubic.

19. Fluat of arsenic. Small crystals.

20. Fluat of mercury. A powder. Before the blowpipe it melts into a yellow glass, most of which evaporates by a continued heat §.

& Scheele OT

SECT. X. Of Carbonats.

THE compounds into which the carbonic acid enters are called carbonats. They were first analysed by 1)r

1. Carbonat of potals. This falt is formed by fatu- Carbonat rating potals with carbonic acid, which is best done by of potals.

expoling a folution of potals for a confiderable time to carbonic acid gas.

It crystallizes, according to Bergman, in quadrangular prisms; the apexes of which are composed of two inverted triangles, converging like the roof a house *. According to Pelletier they are tetrahedral rhomboidal prisms, with dihedral fummits. The complete crystal has eight faces, two hexagons, two rectangles, and four † Ann. dz rhombs †.

It 29.

376 Carbonats. It has an alkaline, but not a caustic taste. does not dissolve above TION parts of it. + Id. It is not altered by exposure to the air. decompose it by compound affinity: Sulphat of lime, Nitrat of barytes, -- barytes, ---- foda, - foda, --- ammonia, ---- magnefia, --- ammonia, alumina, --- magnefia, alumina, Acetite of barytes, Muriat of barytes, lime, ammonia, lime, ammonia, - magnefia, --- magnefia, - alumina, alemina, * Bergman. - foda *, Phosphat of lime ||. The following falts decompose it by compound affi-Its taste and smell, though much weaker, are the nity: fame with those of pure ammonia. Like all the alka-Sulphat of alumina, line carbonats it converts vegetable blues to green, pre-

6. Carbonat of strontites. This falt, which was first Carbonat examined by Dr Hope, is infipid, and foluble in 1536 tites, parts

nate parts of boiling water. It is composed of 30,2 parts of acid, 69,8 of strontites. A violent heat decompoles it +. 7. Carbonat of magnefia. This falt may be formed by faturating the common magnefia of the shops with carbonic acid gas.

et at of It dissolves in water saturated with carbonic acid; g la. and forms by evaporation crystals, which are transparent hexagonal prisms, terminated by a hexagonal plane; these are partly in groups and partly solitary: their fur length is about six lines, their breadth two ‡. They

Mefie. were discovered by Mr Butini of Geneva.

Water at the temperature of 50 diffolves 48 part of Forey, its weight of this falt *. When in the state of powder, and of course deprived of its water of crystallization, it is much more infoluble; and what is very remarkable, it is more foluble in cold than in hot water, impregnated with carbonic acid ‡.

It is composed, according to Foureroy, of 50 parts

of acid, 25 of magnefia, and 25 of water.

When exposed to the air, it effloresces, and falls inroy, to powder .

When heated, it decrepitates, falls into powder, and

is decomposed ‡.

The following falts decompose it by compound affi-

Sulphat of lime, - ammonia,

Nitrat of lime, Muriat of lime, Acetite of lime.

- alumina, 8. Carbonat of alumina. Carbonic acid is capable of diffolving alumina; for if alum be decomposed by an alkaline carbonat, fome alumina remains distolved in the liquor, and may be precipitated by a heat sufficient to nan, drive off the carbonic acid *. It cannot be doubted, then, that there may be produced a carbonat of alumina; but the falt has never been examined with accuracy.

9. Carbonat of iron. Water faturated with carbohats, nic acid diffolves Tofoo part of its weight of iron, nan, which gradually precipitates by exposure to the air ¶. Ruft of iron is a kind of carbonat, at least it always

contains carbonic acid.

10. Carbonat of zinc. Zinc is copiously dissolved 'by water faturated with carbonic acid ‡. As the metallic oxyds, when faturated with carbonic acid, do not differ materially in their appearance from pure oxyds, we shall not attempt to describe any of the metallic car-bonats. We shall, however, present our readers with the following table, exhibiting a view of the weight which metallic oxyds gain by being faturated with this

acid.		
	By Bergman.	By Wenzel
	Precipit

* Plinii, 1. mixture of lime and vinegar in furgery *.

xxvi. c. 24. It crystallizes in fine needles, of a glossy appearance like fatin.

> Its taste is bitter and four, because it has an excess of acid.

It is foluble in water.

9. Acetite of jargonia. This falt may be formed by Acetite pouring acetous acid on newly precipitated jargonia. jargonia It has an astringent taste. It does not crystallize; but when evaporated to drynefs, it forms a powder, which the does not attract moisture from the air as acetite of alu- your. it mina does +. It is very foluble in water and in alco-rby, w s. hol. It is not so easily decomposed by heat as nitrat of jargonia, probably because it does not adhere so flrongly to water *.

10. Acetite of iron. This falt was mentioned by i. Schreeder and Juncker. It is composed of acetous acid

and brown oxyd of iron.

Its folution forms by gentle evaporation small oblong crystals; but the greatest part of the salt assumes the form of a gelatinous mais ‡.

It has a sweetish styptic taste.

According to Wenzel, 240 parts of acetous acid require for saturation 1861 of iron

Heat decomposes this falt : and it seems also to be

gradually decomposed by exposure to the air.

11. Acetite of zinc. This falt was first mentioned by Glauber.

Its crystals are rhomboidal, and sometimes hexagonal plates, of a white colour, and the appearance of talk.

It is soluble in water. According to Wenzel, 240 parts of acetous acid require for faturation 1955ths of zinc.

It is not altered by exposure to the air. Heat decomposes it. When thrown upon burning coals, it explodes with a blue flame.

12. Acetite of manganese. This salt is not crystallizable; and when evaporated to dryness, it deliquesces.

Is it not an acetat?

13 Acetite of cobalt. This falt is deliquescent. Its solution is of a fine red colour while cold; but becomes blue by being heated, and it recovers its former colour on cooling. According to Wenzel, 240 parts of acetous acid require for faturation 2415ths of cobalt.

14. Acetite of nickel. This falt forms rhomboidal cubes of a green colour | : They are not deliquescent:

Their tafte is sweet *.

15. Acetite of lead. This falt is mentioned by Isaac Hollandus and Raymond Lully. It is composed of acetous acid and white oxyd of lead.

It was formerly called fugar of lead, fugar of Saturn, falt of Saturn, vinegar of Saturn, extract of Saturn, &c.

Its crystals are flat parallelopipeds, terminated by two inclined planes approaching each other.

It has a fweet and fomewhat aftringent talte.

It is not very foluble in water; but acetous acid diffolves it abundantly.

According to Wenzel 240 parts of acetous acid require for saturation 503 of lead.

When exposed to the air it becomes yellow, but un-

dergoes no other alteration.

Heat decomposes it by destroying the acid. When diffilled, the refidium takes fire spontaneously on expofure to the air. Paper dipped into acetite of lead forms excellent matches, which are not subject to go out, and which burn very flowly.

The following falts decompose it by compound affi-

Phosphat of ammonia, Muriat of ammonia, Oxalat of potals ||, Sulphat of copper, Phosphat of soda, Malat of potass +, 16. Acetite of tin. This salt was first described by

Its crystals are prismatic needles in groups 1. According to Wenzel, 240 parts of acetous acid require for faturation 311 of tin.

17. Acetite of copper. This falt was known to the Acetites. ancients, and various ways of preparing it are described by Pliny ¶. It was formerly known by the names of Acetite of crystals of Venus and verdigrife.

It is of a deep green colour. Its crystals are rhom- Lib.xxxiv. boids.

It has a disagreeable coppery taste. It is foluble in water and in alcohol.

According to Wenzel, 240 parts of acetous acid require 16 g of copper for faturation.

It effloresces when exposed to the air. Heat decompoles it. It is used in painting.

18. Acetite of bifmuth. This falt feems to have been Acetite of first mentioned by Geoffroi. He called it fugar of bifmuth, bilmuth.

It is most easily procured by mixing together the solutions of nitrat of bismuth and acetite of potals. It forms brilliant, talky, filvery cryftals.

It has a sweetish taste. According to Wenzel, 240 parts of acetous acid require for faturation 155 of bif-

It does not deliquesce when exposed to the air. Heat decomposes it.

19. Acetite of antimony. It yields with difficulty Acetite of fmall crystals +. According to Wenzel, 240 parts of antimony. acetous acid require for faturation 13 of antimony.

20. Acetite of arsenic. This falt forms small crystals Acetite of in grains, hardly foluble in water *. * Bergman.

21. Acetite of mercury. This falt is mentioned by 796 Schræder. Acetite of Its crystals are small thin plates. mercury.

It has a difagreeable tafte, and excites coughing. It is hardly foluble in water. According to Wenzel, 240 parts of acetous acid require for faturation 2407 of mercury.

When exposed to the air it becomes black, owing to the reduction of the oxyd of mercury. Heat decomposes it.

22. Acetite of filver. This falt was perhaps first Acetite of described by Margras.

It is best formed by dropping acetite of soda or pot-

ass into a saturated solution of nitrat of silver +. It forms small oblong crystals, easily dissolved in wa-ibid. tert. It has a sharp taste.

According to Wenzel, 240 parts of acetous acid re-

quire for faturation 1014 of filver.

Heat decomposes it. It is decomposed by muriat of magnesia ¶.

23. Acetite of gold. This falt is mentioned by Acetite of Schroeder and Juncker.

24. Acetite of uranium. This falt was first formed Acetite of by Klaproth uranium.

Its crystals are regular four-sided slender prisms, terminated at both ends by regular quadrilateral pyramids: they are transparent, and of a beautiful topaz yellow colour.

Heat decomposes them: and what is singular, if they be heated gradually red hot, the oxyd which remains retains nearly the form of the crystals *.

* Klaproth The compounds into which the acetic acid enters are on Uranium. called acetats. They are so imperfectly known at pre- Acetats. fent, that we shall not attempt a description of them.

SECT. XII. Of Oxalats.

THE compounds of which oxalic acid forms a part 3 B 2

Oxalats. are known by the name of oxalais. They were first described by Bergman. 801

1. Oxalat of potals. This falt crystallizes with dif-Oxalat of ficulty. It is very foluble in water. When heated it potafs. 1 Bergman, falls to powder +.

1. 262. Acidulous oxalat of potafs.

2. Acidulous oxalat of potafs. The oxalic acid is also capable of combining with potass in excess, and forming another falt, called acidulous oxalat from its acid taste; or, to speak more accurately, this salt is formed by the combination of oxalat of potals with oxalic acid. This falt exists ready formed in oxalis acetofella or woodforrel; from which it is extracted in some parts of Europe in great quantities. Hence it was formerly called falt of wood forrel. It is mentioned by Duclos in the Memoirs of the French Academy for 1668. Margraf first proved that it contained potass; and Scheele discovered that its acid is the oxalic. A great many interesting experiments had been previously made on it by Wenzel and Wiegleb.

It may be formed, as Scheele has shown, by dropping potals very gradually into a faturated folution of oxalic acid in water: as foon as the proper quantity of alkali is added, acidulous oxalat is precipitated. But care must be taken not to add too much alkali, otherwise

no precipitation will take place at all.

\$ De Lifte. Its crystals are small opaque parallelopipeds t. It has an acid, poignant, bitterish, taste.

It is foluble in about ten times its weight of boiling water, but much less soluble in cold water.

It is not altered by exposure to the air. Heat decomposes it.

This falt is fold in this country under the name of

essential falt of lemons.

3. Oxalat of foda. This falt agrees very much with Oxalat of oxalat of potass. Its crystals are small, and soluble in

> From Bergman's description, oxalic acid appears also capable of combining in excess with soda, and forming an acidulous oxalat.

803

foda.

4. Oxalat of ammonia. Its crystals are four-fided prisins, generally diverging from various points. They redden the infusion of turnsole.

They are easily soluble in water, but not in alcohol t.

¶ Bergman, It is decomposed by nitrat of barytes ¶.

5. Oxalat of barytes. This falt does not crystallize except with excess of acid. The addition of potafs, or Earthy oxeven of water, deprives it of this excess, and then it crumbles into powder. It is infoluble in water +.
6. Oxalat of lime. This falt does not crystallize. + Bergman,

It is infoluble in water, but somewhat soluble in acids. It is composed of 48 parts of acid; 46 of lime, and 6 of

\$ Bergman, water. Heat decomposes it \$\pm\$.

7. Oxalat of strontites. This falt was first formed by Dr Hope. It is a white infipid powder; foluble in 1920 parts of boiling water. Heat decomposes it

Hope, by destroying the acid To Trans. Edin.

8. Oxalat of magnesia. This falt is in the form of a white powder. It is scarcely foluble either in water or alcohol. It is composed of 35 parts of magnefia

† Bergman, and 65 of acid and water. Heat decomposes it †.
ibid. and ii. 9. Oxalat of alumina. It is uncrystallizable; but furnishes on evaporation a yellowish pellucid mass. It is sparingly soluble in alcohol. It has a sweet astringent tafte. It is composed of 44 parts of alumina and 56 of acid and water.

When exposed to the air it deliquesces; and if it has O been previously well dried, its weight is increased by 3. It reddens turnsol ¶.

10. Oxalat of iron. This falt forms prilinatic cry-ibid.

stals of a yellowish-green colour.

It has an astringent and sweet taste. It is very so-oxal luble in water.

It is composed of 45 parts of green oxyd, and 55 of acid and water. When exposed to heat it falls to pow-

From Bergman's description, the brown oxyd of iron appears also capable of combining with oxalic acid. The compound does not crystallize, and is nearly info-

11. Oxalat of zinc. It is hardly foluble in water. It is composed of 75 parts of oxyd and 25 of acid.

12. Oxalat of manganele. It is composed of oxalic acid and white oxyd of manganese. It appears capable of crystallizing ¶.

13 Oxalat of cobalt. This is a rofe-coloured powder, insoluble in water, but soluble in oxalic acid; and capable, by that means, of crystallizing 1.

14. Oxalat of nickel. This is a green coloured powder, hardly foluble in water. It is compoled of two parts of acid and one of oxyd ¶.

15. Oxalat of lead. It forms small crystalline grains. They are infoluble in alcohol, and nearly infoluble in water. They contain 55 parts of oxyd and 45 of acid ||. || Ibia

16. Oxalat of tin. This falt forms prismatic crystals. It has an austere taste. If the solution of this salt be quickly evaporated, it affords a mais refembling horn, and foluble in water ‡.

7. Oxalat of copper. This falt is uncrystallizable. It is a bluish powder, infoluble in water, except with excess of acid. It is composed of 21 parts of copper and 29 of acid ||. | Ibid

18. Oxalat of bismuth. This falt may be formed by dropping oxalic acid into a folution of nitrat of bifmuth. It forms pellucid polygonous cryftals. When oxyd of bifmuth is diffolved by oxalic acid, the refult is a white powder, scarcely foluble in water *.

19. Oxalat of antimony. This falt forms crystalline

grains, with difficulty foluble in water +.

20. Oxalat of arfenic. This falt is composed of oxalic acid and white oxyd of arlenic. Its crystals are prisms very foluble in water and alcohol. It reddens turnfole.

Heat fublimes it; and by a strong heat it may be de-

21. Oxalat of mercury. A white powder hardly foluble in water, except with excess of acid t. ‡ Ibid.

22. Oxalat of filver. This falt may be formed by pouring oxalie acid into a folution of nitrat of filver-It is a white powder, fearcely foluble in water, and not at all in alcohol; but foluble in nitric acid. It becomes black by being exposed to the air, owing to the reduction of the oxyd ||.

23. Oxalat of platinum. This falt affords yellow crystals.

SECT. XIII. Of Tartrites.

THE falts into which tartarous acid enters as an ingredient are known by the name of tartrites.

1. Acidulous oxalat of potass or tartar. This salt, Tartar which is composed of potals and an excess of tartarous acid, or rather of tartrite of potals and tartarous acid,

ken de Sale

es. has been long known. It is obtained in a state of impurity at the bottom, and adhering to the fides of casks in which wine has fermented. It is called tartar, fays Paracellus, because it produces the oil, water, limestone, and falt, which burn the patient as Hell does. According to him, it was the principle of every difease and every remedy, and all things contain the germ of it.

Margraf and Rouelle first demonstrated that it contained potals ready formed: and Scheele first obtained

tartarous acid from it in a state of purity.

Its crystals are very small and irregular. According to Montet, they are prisms, somewhat flat, and mostly with fix fides. It has a strong acid taste. It is soluble d. in about 30 times its weight of boiling water ¶. According to Bergman, it contains 23 parts of alkali and 77 of acid.

It is not altered by exposure to the air. Heat decomposes it, and at the same time destroys the acid. It

is capable of forming a great many compounds
2. Partrite of potafs. This falt may be formed by faturating the last described falt with potals. It was formerly called foluble tartar, because it is much more foluble in water than the acidulous tartrite of potais. It crystallizes most readily when there is a small excess of alkali in the folution. Its crystals are small oblongs.

It has an unpleasant bitter taste. It is soluble in 4

parts of water, at the temperature of 40°.

3. Tartrite of foda This falt has never been accu-

rately examined.

4. Tartrite of potals and foda. This triple falt, formerly known by the name of falt of Seignette, because first formed by Mr Seignette apothecary at Rochelle, is made by faturating tartar with foda.

Its crystals are prisms of eight or ten unequal sides, having their ends truncated at right angles. They are generally divided into two in the direction of their axes, and the base on which they stand is marked with two diagonal lines, fo as to divide it into four triangles.

It has a bitter tafte. It is almost as foluble as tar-

trite of potafs.

It effloresces when exposed to the air. Heat de-

composes it.

4. Tartrite of ammonia. The crystals of this salt lia. are polygonous prisms, not unlike those of the last deferibed falt.

It has a cooling bitter tafte like that of nitre. It is

easily soluble in water. Heat decomposes it.

5. Acidulous tartrite of ammonia. This falt may be formed by pouring tartarous acid into a folution of tartrite of aminonia. Like acidulous tartrite of potaís it is very infoluble in water.

6. Tartrite of potats and ammonia. This triple falt may be formed by pouring ammonia into acidulous tar-

trite of potals.

Its crystals, according to Macquer, are prisms with four, five, or fix fides: according to the Dijon academicians, parallelopipeds, with two alternate sloping fides.

It has a cooling tafte. It is foluble enough in water. It effloresces in the air. Heat decomposes it.

7. Tartrite of barytes. Unknown.

8. Tartrite of lime. This falt, first formed by Scheele, is a tasteless and almost insoluble powder. By heat the acid is decomposed, and the pure lime remains behind.

9. Tartrite of strontites. This falt was first formed by Dr Hope. Its crystals are small regular triangular tables, having the edges and angles sharp and well de-

fined. It is insipid. It dissolves in 320 parts of boil- Tartrites.

It is not altered by exposure to the air. Fleat de- * Hope, composes it by destroying the acid *.

10. Tartrite of magnetia. This falt is infoluble iniv. 15. water except there be an excess of acid present. It then affords by evaporation small crystals in the form of hexangular truncated prisms +.

It has a more faline tafte, and is more fufible than it. 288. t Von Puc-

tartrite of lime 1.

Heat first melts and afterwards decomposes it.

Heat first melts and afterwards decomposes it.

11. Partrite of alumina. This falt does not crystal-Tartar. lize, but forms by evaporation a clear transparent gummy mals. Its tafte is aftringent. It is toluble in wa-* Von Pac-It does not deliquesce in the air *.

12. Tartrite of potass and alumina This triple salt ken. is formed by faturating tartar with alumina. It bears a very firiking refemblance to the last described falt.

13. Tartrite of iron. This is a grey powder. When Metallic tartarous acid is poured into a folution of fulphat oftartrites. iron, scaly crystals are formed by evaporation. These cryitals are doubtless composed of tartarous acid combined with fulphat of iron. This triple falt might be called tartro-fulphat of iron.

14. Partrite of potais and iron. This triple falt was formerly called tartarifed tincture of Mars, chalybeated tartar, and tartarifed iron. It may be formed by boiling two parts of tartar and one of iron filings, previously made up into a paste, in a proper quantity of water. The liquor by evaporation deposits crystals, which form the falt wanted.

15. Tartrite of zinc. This falt is not easily soluble

in water.

16. Tartrite of potass and zinc. This triple salt, formed by combining tartar and oxyd of zinc, is very foluble in water ‡.

17. Tartrite of lead. This falt, which is composed de Chim. of tartarous acid and white oxyd of lead, is almost info-Dijon. luble in water. Nitric acid dissolves it

18. Tartrite of potals and lead. This falt, formed by combining white oxyd of lead with tartar, is very foluble in water *.

19. Tartrite of tin. Unknown. The tartrite of potass and tin, composed of tartar and oxyd of tin, is capable of crystallizing.

20. Tartrite of copper. This falt is best formed by pouring tartarous acid into the folutions of muriat or fulphat of copper; it precipitates in the form of blue

A Bergman. cryitals ¶. This talt forms the best kind of the pigment called

Brunswick green 1. 21. Tartrite of potass and copper. This triple salt is also in the form of blue crystals.

22. Tartrite of bismuth. Small crystalline grains | Bergmans

23. Tartrite of antimony. This falt has never been examined with attention.

24. Tartrite of potals and antimony, or tartar emetic. To this falt, which is perhaps the most powerful emetic known, a great deal of attention has been paid, and a vast number of methods have been tried to prepare it. These methods have been already described in the Encyclopædia. It appears from the experiments of Mr. Bindheim, that if this falt be carefully prepared, the difference that results from the use of different oxyds is

not fo great as might have been expected +. It was first made known by Adrian in 1631. Citrats. a triple falt, composed of tartar and white oxyd of antimony.

It is of a white colour and transparent. Its crystals

are trihedral pyramids.

It dissolves in 60 parts of cold water, and in a smaller proportion of hot water. It is decomposed by lime and alkalies, iron, &c. Care ought therefore to be taken to use only distilled water when it is administered as a medicine.

25. Tartrite of arfenic. This falt forms prismatic Bergman, crystals very like those of oxalat of arfenic ¶.

26. Tartrite of mercury. A yellow powder.

27. Tartrite of potass and mercury. This triple salt of Monnet. crystallizes +.

SECT. XIV. Of Citrats.

THE compounds into which the citric acid enters have been denominated citrats.

These salts are at present very impersectly known. * Jour. de Mr Dizé has promised soon to supply this defect *. I Citrat of potafs. This falt does not crystallize. Supplement. It has a cooling faline taste, and deliquesces when ex-

posed to the air. Alkaline

2. Citrat of foda. This falt does not deliquesce. It citrats.

has a mild, pleasant, cooling taste ¶. According to Dr Donald Monro, Scheele, it does not crystallize. Phil. Trenf. 3. Citrat of ammonia. This falt crystallizes in thin

5. Citrat of lime. This is a white powder, scarcely

foluble in water | . | Id.

6. Citrat of magnefia. Does not crystallize. forms a gummy faline mass very soluble in water 1.

7. Citrat of alumina. This falt is fcarcely foluble in

815 8. Citrat of iron. A folution of a brown colour. Metallic citrats.

9. Citrat of copper. A green gummy mass.
10. Citrat of mercury. This salt may be formed by pouring citric acid into nitrat or acetite of mercury. It is a flaky falt, of a brick dust colour, more or less red +.

SECT. XV. Of Malats.

THE compounds into which the malic acid enters are called malats. This class of falts was first discovered by Scheele. They are no better known than the citrats.

816 Malats. \$ Scheele.

A Id.

H ld.

+ 1d.

† Dizé.

1. Malat of potafs. 2. Malat of ioda. These salts are deliquescent . 3. Malat of ammonia.

4. Malat of lime. Small irregular crystals. They require a large quantity of boiling water for their folution. With excess of acid they are readily soluble in cold water s. They are infoluble in alcohol ||.

5. Malat of barytes. The properties of this falt refemble pretty much those of malat of lime T.

\$1d. 6. Malat of magnefia. Deliquescent ‡.

7. Malat of iron. A brown folution, not crystallizable +.

9 ld.

SECT. XVI. Of Lactats.

THE neutral falts formed by the combination of the late lactic acid with various bases are called lactats. They were first discovered by Scheele.

1. Lactat of potals. A deliquescent salt, soluble in alcohol f.

2. Lactat of foda. This falt does not crystallize. It Mills is foluble in alcohol +.

3. Lactat of ammonia. Crystals which deliquesce. Heat separates a great part of the ammonia before destroying the acid.

4. Lactat of barytes.
5. Lactat of lime.
6. Lactat of alumina.
6. Lactat of alumina.
7. These falts deliquesces. The state of lime is soluble in alcohol to the state of lime is foluble in alcohol to the state of lime is foluble in alcohol to the state of lime is folible.

7. Lactat of magnefia Small deliquescent crystals | . | 1812

8. Lactat of iron. A brown folution.
9. Lactat of zinc. Crystals *.

These salts have a very strong resemblance to malats. The only difference which Scheele observed was, that the malat of lime was infoluble in alcohol, while alcohol dissolved lactat of lime.

SECT. XVII. Of Saccholats.

THE compounds into which the faceholactic acid en-Sacche ters are called faccholats. They also were first discovered by Scheele.

1. Saccholat of potafs. Small crystals, foluble in eight times their weight of boiling water *.

2. Saccholat of foda. The fame; soluble in five Sugar times their weight of boiling water f.

3. Saccholat of ammonia. A falt which has a fourish & Ibid. tafte. Heat separates the ammonia +.

4. Saccholat of barytes. 5. Saccholat of lime. These salts are insoluble

6. Saccholat of magnefia. (in water ¶. I Ibid. 7. Saccholat of alumina.

SECT. XVIII. Of Gallats.

THE compounds into which the gallic acid enters are Gallats denominated gallats. They were first attended to by the Dijon academicians and by Scheele.

. Gallat of potafs. We only know that these 2. Gallat of foda.

2. Gallat of foda.

3. Gallat of ammonia. and that their properties are different from those of all other falts.

4. Gallat of barytes. These falts are soluble in wa-5. Gallat of lime. Ter, especially when there is excess of acid.

6. Gallat of magnefia. This falt is a yellow powder, soluble in water and in alcohol |.

7. Gallat of alumina. This falt, according to Bar- Barth tholdi, exits ready formed in nut galls. It is very for Chim. xii luble in water.

8. Gallat of iron. This falt, which Mr Prouft has discovered to be formed of gallic acid and brown oxyd of iron, is of a black colour, and does not feem capable of crystallizing. It is soluble in the three mineral acids, and by that means is deprived of its black colour. It is to this falt that ink partly owes its black colour. Gallat of iron is decomposed by alkalies.

We shall not attempt any farther account of this class 8. Malat of zinc. This falt forms beautiful crystals q. of falts. Scarcely any addition has yet been made to

ready in the article CHEMISTRY, Encycl.

SECT. XIX. Of Benzoats.

have been called benzoats.

1. Benzoat of potals. This falt forms pointed feathery crystals. It has a saline sharp taste. It is very foluble in water. It deliquesces when exposed to the

air ¶.
2. Benzoat of foda. The crystals of this salt are larger, but its tafte is the same with that of benzoat of potaís. It is also very soluble in water. It effloresces

in the air +.

3. Benzoat of ammonia. This falt crystallizes with difficulty. Its crystals are feather-shaped. It deli-

4. Benzoat of lime. This falt forms white, shining, pointed crystals, of a sweetish taste, and not easily soluble in water §.

5. Benzoat of magnefia. Feather-shaped crystals, of a sharp bitter talte, and easily soluble in water ||.

6. Benzoat of alumina. An aftringent falt.
7. Benzoat of iron. This falt forms yellow cryftals. It has a sweet taste. It is soluble in water and alcohol. 7, It effloresces in the air. Heat disengages the acid †. 8. Benzoat of zinc. This salt forms arborescent cry-

It is foluble in water and alcohol. When ex-

posed to the air it is diffipated. Heat decomposes it ‡.

9. Benzoat of manganese. This salt, which is formed of benzoic acid and white oxyd of manganele, crystallizes in small scales. It dissolves readily in water, with difficulty in alcohol. It is not altered by exposure to the air ¶.

10. Benzoat of cobalt. Flat crystals ‡.

11. Benzoat of lead. Very white crystals, foluble in water and alcohol. They are not altered by exposure

to the air. Heat disengages the acid ||.

12. Benzoat of tin. This salt may be formed by pouring henzoat of potals into a folution of tin in the nitro-muriatic acid. The benzoat of tin is precipitated. It is foluble in hot water, but infoluble in alcohol. Heat decomposes it \$.

13. Benzoat of copper. Small crystals of a deep green colour. They are with difficulty foluble in water,

and not at all in alcohol +.

14. Benzoat of bismuth. This salt forms white needle-shaped crystals. They are soluble in water and in a very small proportion in alcohol. They are not altered by exposure to the air. Heat decompose

15. Benzoat of antimony. Crystals which effloresca

in the air, and are decomposed by heat ||.

16. Benzoat of arfenic. Small feather-shaped crystals. It is soluble in hot water, but crystallizes in the cooling. A moderate heat sublimes it; a strong heat decomposes it. Sulphur decomposes it. It is not decomposed by alkalies ‡.

17. Benzoat of mercury. A white powder. It is insoluble in water, but dissolves in a small quantity in alcohol. It is not altered by exposure to the air. A small heat sublimes it; a greater decomposes it. It is

decomposed by sulphur †.

18. Benzoat of silver. This salt is soluble in water

the experiments of Scheele which have been given al- and also in a very small proportion in alcohol. It is Camphonot altered by exposure to the air, but the rays of the rats. fun render it brown. Heat disengages its acid ||.

SECT. XIX. Of Benzoats.

altered by exposure to the air. Heat decomposes it ¶.¶ Id. ibid.
20. Benzoat of platinum. This salt forms small brownish crystals, with difficulty soluble in water; not foluble in alcohol. When exposed to heat, it is decompo-§ Id. ibid. fed, and there remains behind a brown powder s.

SECT. XX. Of Succinats.

THE neutral falts, formed by the combination of the fuccinic acid with various bases, have been called succi-

We shall not describe these salts, as we could not add much to the account given in the Appendix to the article CHEMISTRY in the Encyclopædia. That account was taken from Mr Kier's Chemical Dictionary, and that gentleman borrowed it from Leonhardi.

SECT. XXI. Of Camphorats ..

THE neutral falts into the composition of which cantphoric acid enters, have been denominated camphorats. The only chemist who has hitherto examined them is Bouillon la Grange: his experiments have been publish-

ed in the 27th volume of the Annales de Chimie.

1. Camphorat of potass To prepare this falt car- Camphorat bonat of potals is to be diffolved in water, and the folu- of potals. tion faturated with camphoric acid. When the effervefcence is over, the liquor is to be evaporated by a gentle heat to the proper confiftence, and crystals of camphorat of potals will be deposited when the liquor cools.

Camphorat of potals is white and transparent; its erystals are regular hexagons. Its taste is bitterish and

flightly aromatic.

Water at the temperature of 600 diffolves rooth part of its weight of this falt; boiling water diffolves the part of its weight.

It is foluble in alcohol, and the folution burns with a

deep blue flame.

When exposed to moist air, it loses a little of its

transparency, but in dry air it suffers no change.

When exposed to hear it melts, swells, and the acid is volatilized in a thick smoke, which has an aromatic odour. Before the blow-pipe it burns with a blue flame, and the potass remains behind in a state of purity.

By compound affinity this falt is decomposed by

Nitrat of barytes, All the falts whose base is lime, Nitrat of filver, Sulphat of iron, Muriat of tin, - lead *.

2. Camphorat of foda. This falt may be formed La Grange, precisely in the same manner with the camphorat of Ann. de Chim. xxvii.

It is white and transparent; its taste is somewhat 24. bitter; its crystals are irregular.

Water at the temperature of 600 dissolves less than of soda. 2 to of its weight of this falt; boiling water diffolves ith of its weight.

It is also soluble in alcohol.

When exposed to the air it loses its transparency, and

Campho- effloresces slightly, but is never completely reduced to powder.

Heat produces the same effect upon it as on camphorat of potals: the acid burns with a blue flame, which becomes reddish towards the end.

By compound affinity it is decomposed by Nitrat of lime, Muriat of lime, - filver, _____ iron, Muriat of magnesia, Sulphat of alumina, - barytes, --- iron; and ma-- alumina, ny other falts with me-

* Bouillon tallic bases *.

3. Camphorat of ammonia. This falt may be pre-Ann. de Chim. xxvii. pared by diffolving carbonat of ammonia in hot water, and adding camphoric acid flowly till the alkali is fatu-S25 rated. It must then be evaporated with a very moderate heat, to prevent the disengaging of ammonia.

Camphorat

& Ibid.

826

It is very difficult to obtain this falt in regular crystals. When evaporated to dryness, there is obtained a folid opaque mass of a sharp and bitterish taste.

Water at the temperature of about 60° dissolves nearly Tooth part of its weight of this falt; boiling water diffolves Id of its weight: But this and the two falts above described are a good deal more soluble when there is excels of bale.

It is entirely foluble in alcohol.

When exposed to the air it attracts moisture, but not in sufficient quantity to enable it to assume a liquid

When exposed to heat it swells, melts, and is converted into vapour; before the blow pipe it burns with a blue and red flame, and is entirely volatilized.

Most of the calcareous falts form triple falts with

camphorat of ammonia.

It decomposes in part all the aluminous falts except

the fulphat of alumina +.

4. Camphorat of barytes. In order to prepare this Camphorat falt, barytes is to be diffolved in water, and camphoric of barytes. acid added to the folution; the mixture is then to be boiled, and afterwards filtered and evaporated to dry-

Camphorat of barytes does not crystallize; when the of lime. evaporation is conducted flowly, the falt is deposited in thin plates one above another, which appear transparent while immerfed in the liquor, but become opaque whenever they come into contact with the air.

It has very little tafte, though it leaves at last upon the tongue a flight impression of acidity mixed with bit-

Water diffolves only a very small quantity of this falt: boiling water being capable of taking up only ath part of it.

It is not altered by exposure to the air.

When exposed to heat it melts easily, and the acid is volatilized. When the heat is confiderable, the acid burns with a lively blue flame, which becomes red and at last white.

It is decomposed by

Nitrat of potals, soda, lime, ammonia, and magnesia. Muriat of lime, potafs, alumina, and magnefia.

All the fulphats.

Carbonat of potals and foda.

La Grange, Carbonat of potats and rocas.

5. Camphorat of lime. This falt may be prepared Camphorat by dropping into lime-water crystallized camphoric acid. part of its weight of this falt. Boiling water diffolves

The mixture is then to be made boiling hot, paffed C through a filter, and evaporated to about 3ths of its volume. On cooling camphorat of lime is deposited.

It has no regular shape; but if the evaporation has been properly conducted, it is in plates lying one above an-It is of a white colour, and has a taste slightly

Water at the temperature of 60° dissolves very little of this falt; boiling water is capable of diffolving about zooth part of its weight of it. It is infoluble in alco-

It is composed of 43 parts of lime, 50 of acid, and 7 of water.

When exposed to the air it dries and falls into pow-

When exposed to a moderate heat it melts and swells up: when placed on burning coals, or when heated in close vessels, the acid is decomposed and volatilized, and the lime remains pure.

When sulphuric acid is poured into a solution of this falt, it produces an infoluble precipitate; nitric and muriatic acids precipitate the camphoric acid.

It is decomposed by compound affinity by

Carbonat of potals, Nitrat of barytes, Muriat of alumina, Sulphat of alumina, Phosphat of soda *.

6. Camphorat of magnefia. This falt may be pre-La pared by pouring water on carbonat of magnefia, and Ann then adding crystallized camphoric acid: heat is then Chim applied, the folution is filtrated, and evaporated to dry-210 ness. The falt obtained is diffolved in hot water, passed Cam through a filter, and evaporated by means of a mode-of m rate heat till a pellicle forms on the furface of the folu-fia, tion. On cooling the falt is deposited in thin plates. The fecond folution is to remove any excess of magnefia that may happen to be present.

This falt does not crystallize. It is white, opaque, and has a bitter taste.

It is scarcely more soluble in water than camphorat

Alcohol has no action on it while cold, but when hot it disfolves the acid and leaves the magnesia; and the acid precipitates again as the alcohol cools.

When exposed to the air it dries and becomes covered with a little powder; but this effect is produced

flowly, and only in a warm place.

When this falt is placed on burning coals, the acid is volatilized, and the magnefia remains pure. Before the blow-pipe it burns like the other camphorats with a blue flame.

The nitrats, muriats, and fulphats, do not completely decompose this falt, if we except the nitrat of lime and muriat of alumina *.

7. Camphorat of alumina. To prepare this falt, alumina, precipitated by means of ammonia, and well wash. Camp ed, is to be mixed with water, and crystals of campho- of alum ric acid added. The mixture is then to be heated, filtered, and concentrated by evaporation...

This falt is a white powder, of an acid bitterish taste, leaving on the tongue, like most of the aluminous salts,

a fensation of astringency.

Water at the temperature of 60° dissolves about 100 th

it in considerable quantities; but it precipitates again as the folution cools.

Alcohol, while cold, diffolves it very sparingly; but when hot it diffolves a confiderable quantity of it, which precipitates also as the folution cools.

I'his falt undergoes very little alteration in the air;

but it rather parts with than attracts moisture.

Heat volatilizes the acid; and when the falt is thrown on burning coals it burns with a blue flame.

It is decomposed by the nitrats of lime and ba-

SECT. XXII. Of Suberats.

ii. The falts formed by the suberic acid have obtained the appellation of fuberats. They have hitherto been examined only by Bouillon la Grange.

1. Suberat of potals. This falt ought to be formed

by means of crystallized carbonat of potals.

It crystallizes in prisms, having four unequal sides. It has a bitter faltish taste, and it reddens vegetable It is very foluble in water. Caloric melts it, and at last volatilizes the acid.

It is decomposed by most of the metallic salts, and by fulphat of alumina, muriat of alumina, and of lime; nitrat of alumina and of lime; and phosphat of alu-

2. Suberat of foda. This falt does not crystallize. It reddens the tincture of turnfole. Its taffe is flightly bitter. It is very foluble in water and in alcohol. It attracts moissure from the air. Caloric produces the fame effect on it that it does on suberat of potals.

It is decomposed by the calcareous, aluminous, and

magnefian falts ‡.

3. Suberat of ammonia. This falt crystallizes in parallelopipeds. Its tafte is faltish, and it leaves an impreffion of bitterness: It reddens vegetable blues.

It is very soluble in water. It attracts moisture from the air. When placed upon burning coals, it lofes its water of crystallization, and swells up; and before the blow-pipe it evaporates entirely.

It is decomposed by the aluminous and magnesian

4. Suberat of barytes. This falt does not crystallize. Heat makes it swell up, and melts it. It is scarcely soluble in water except there be an excess of acid.

It is decomposed by most of the neutral falts except

the barytic falts and the fluat of lime ||.

5. Suberat of lime. This falt does not crystallize. of It is perfectly white: it has a faltish taste: it does not redden the tincture of turnsole.

It is very sparingly soluble in water except when hot; and as the folution cools most of the falt precipitates

When placed upon burning coals it swells up, the acid is decomposed, and there remains only the lime in the state of powder.

It is decomposed by

The muriat of alumina, The carbonats of potass and soda, The fluat of magnefia,

The phosphats of alumina and soda,

The borat of potals,

All the metallic folutions ¶.

6. Suberat of magnefia. This falt is in the form of of a powder: it reddens the tincture of turnsole. It has a

SUPPL. VOL. I. Part I.

bitter taste: it is soluble in water, and attracts some Prussiats. moisture when exposed to the air.

When heated it swells up and melts: before the blow pipe the acid is decomposed, and the magnesia remains in a state of purity.

It is decomposed by

Muriat of alumina, Nitrat of lime and alumina, Borat of potals, Fluat of foda,

Phosphat of alumina *.

SECT. XXIII. Of Pruffiats.

THE compounds into which the pruffic acid enters

are called Pruffiats

These substances, the most important of which are triple falts, have fomething very peculiar in their affinities. The pruffic acid appears to have a stronger affinity for alkalies and earths than for metals, at least these fubstances are capable of decomposing metallic prussiats; yet acids fearcely decompose the metallic pruffiats, while the weakest acid known decomposes the pruffiats of alkalies and earths. These phenomena have not yet been fatisfactorily accounted for.

1. Prussiat of potass. These salts were first ob- Alkaline 2. Prussiat of soda. tained pure by Mr Scheele. They are foluble in water; but they are of little use, as mere exposure to the air decomposes them

3. Prussiat of ammonia. This falt has the smell of ammonia. It is very volatile and as cafily decomposed as the other two.

4. Pruffiet of lime This filt is foluble in water. Earthy It is also decomposed by exposure to the air.

5. Pruffiat of barytes. 3
6. Pruffiat of magnefia Thefe falts are also fo-

luble in water, and decomposed by all acids.

Pruffic acid does not combine with alumina. 7. Pruffiat of iron, or Pruffian blue. This substance Pruffian is composed, as Mr Proust has shewn, of the prussic blue. acid and brown oxyd of iron With the green oxyd the pruffic acid forms a white compound, which, however, becomes gradually blue when exposed to the atmosphere, because the oxyd absorbs oxygen and is con-

verted into brown oxyd ||. Prustiat of iron is a deep blue coloured powder. It Journal, i.

Nicholfon's

840

Affinities

plained.

Pruffiats, is infoluble in water, and fearcely foluble in acids. It is composed, according to the most accurate experiments hitherto made, of equal parts of oxyd or iron and pruffic acid. It is not affected by exposure to the air Heat decomposes it by destroying the acid, and the oxyd of iron remains behind.

The Prussian blue of commerce, besides other impurities, contains mixed with it a great quantity of alumina. Its use as a pigment, and the attempts which have been made to introduce it as a dye, are well known.

Prussiat of iron may also exist in another state: It may have a superabundance of oxyd; its colour is then more or less yellow. To this flate it may be reduced by digeffing it with alkalies or any of the alkaline earths. These substances deprive it of part of its acid, but not of the whole.

This yellow pruffiat is foluble in acids

Were we to attempt an explanation of this, and the fic acid ex. other phenomena which the pruffic acid difplays in its combinations, we would conjecture, that this yellow pruffiat is the fubstance formed by the direct combination of brown oxyd of iron and pruffic acid, and that the blue pruffiat is formed of the yellow pruffiat combined as an integrant with pruffic acid: That the affinity bet ween the pruffic acid and oxydof iron is much stronger than that between yellow pruffiat of iron and pruffic acid: that therefore alkalies and earths have a stronger affinity for pruffic acid than the yellow pruffiat has, but a much weaker affinity than oxyd of iron, and perhaps every other oxyd; hence the apparent fuperiority of alkalies and earths in some cases, while in others they appear very inferior. We would suppose, then, that the pruffic acid has a much stronger affinity for oxyd of iron, and perhaps for all other oxyds, than for other bodies; that the pruffiats, thus formed, are capable of combining with pruffic acid; but that their affinity for it is much less than that of the alkalies and earths. This conjecture is supported by all the phenomena at present known; it would remove all the apparent anomalies which the combinations of this fingular acid present, and reduce the whole of them under the known laws of affinity.

841 Properties of Prussian alkali,

8. Pruffiat of potafs and iron, commonly called Prufsian alkali, or Prussian test. This substance is a triple falt, composed of prussic acid, potase, and oxyd of iron combined together. To chemists and mineralogists it is one of the most important instruments ever invented; as, when properly prepared, it is capable of indicating whether any metallic substance (platinum excepted) be present in any solution whatever, and even of pointing out the particular metal, and of ascertaining its quantity: This it does by means of a compound affinity, which, after what has been faid above, may be easily understood. The Prussian alkali may be conceived to be a combination of two fubstances, prussiat of potass and blue prussiat of iron. Now every metallic oxyd has a stronger affinity for prussic acid than potass has (and, in fact, seems to have a stronger affinity for it than for any other substance). If, therefore, there happen to be any oxyd in the folution, it immediately feizes the pruffic acid with which the potass is combined, and by that means decomposes the triple salt. A pruffiat of the particular metal is formed, and, as most pruffiats of metals are infoluble, it is precipitated; and it indicates by its colour the particular metal, and by

its weight the quantity of metal that happens to be broth At the same time, the blue prussiat of iron is also precipitated, and its weight must be deducted from the quantity of the precipitate.

In order to be certain of the accuracy of these refults, it is necessary to have a Prushan alkali perfectly pure, and to be certain before hand of the quantity, or rather of the proportions of its ingredients. To obtain a test of this kind has been the object of chemists ever fince the discoveries of Macquer pointed out its importance. It is to the use of impure tells that a great part of the contradictory refults of mineralogical analyses by different chemists is to be ascribed.

There are two ‡ ways in which this tell may be ren- ! See dered impure, belides the introduction of foreign in wan's gredients, which we do not mention, because it is obvious that it must be guarded against. 1. There may be Liable a superabundance of alkali present, or, which is the impur fame thing, there may be mixed with the Pruffian test a quantity of pure alkali; or, 2. There may be contained in it a quantity of yellow pruffiat of iron, for which prussiat of potals has also a considerable affinity.

If the Prussian test contain a superabundance of alkali, two inconveniences follow. This superabundant quantity will precipitate those earthy falts which are liable to contain an excess of acid, and which are only foluble by that excess: Hence alumina and barytes will be precipitated. It is to the use of impure tests of this kind that we owe the opinion, that barytes and alumina are precipitated by the Prussian alkali, and the confequent theories of the metallic nature of these earths. This mistake was first corrected, we believe, by Mr Klaproth.

Another inconvenience arising from the superabundance of alkali in the Prussian test is, that it gradually decomposes the blue prussiat which the test contains, and converts it into yellow pruffiat. In what manner it does this will be understood, after what has been said,

without any explanation.

On the other hand, when the Prussian alkali contains a quantity of yellow pruffiat of iron, as great inconveniences follow. This yellow pruffiat has an affinity for pruffic acid, which, though inferior to that of the potass, is still considerable; and, on the other hand, the potass has a stronger affinity for every other acid than for the pruffic. When, therefore, the test is exposed to the air, the carbonic acid, which the atmosphere always contains, affisted by the affinity between the yellow pruffiat and the pruffic acid, decomposes the pruffiat of potals in the test; and the yellow pruffiat is precipitated in the form of Prussian blue: And every other acid produces the same effect. A test of this kind, therefore, would indicate the presence of iron in every mixture which contains an acid (for a precipitation of Prussian blue would appear); and could not, therefore, be trusted to with any confidence

We will not attempt to describe the various methods Klaprob which different chemists have adopted of preparing this method test; but shall satisfy ourselves with describing the forming method of Klaproth, which answers the purpose completely. This we shall do nearly in the words of Mr.

Prepare a pure potals, by gradually projecting into a large crucible heated to whiteness a mixture of equal parts of purified nitre and crystals of tartar; when the whole hour, to burn off the coal.

Detach the alkali thus obtained from the crucible, reduce it to powder, spread it on a muffle, and expose it to a white heat for half an hour.

Diffolve it in fix times its weight of water, and filter

the folution while warm.

Pour this folution into a glass receiver, placed in a fand furnace, heated to 170° or 180°, and then gradually add the best Prussian blue in powder. injecting new portions according as the former becomes grey, and supplying water as fast as it evaporates; continue until the added portions are no longer discoloured, then increase the heat to 212° for half an hour.

Filter the ley thus obtained, and faturate it with sulphuric acid moderately diluted; a precipitate will appear; when this ceases, filter off the whole, and wash

the precipitate.

Evaporate the filtered liquor to about one quarter, and fet it by to crystallize: after a few days, yellowish crystals of a cubic or quadrangular form will be found mixed with some sulphat of potass and oxyd of iron; pick out the yellowish crystals, lay them on blotting paper, and rediffolve them in four times their weight of cold

water, to exclude the fulphat of potafs.

7. Essay a few drops of this solution with barytic water, to fee whether it contains any fulphuric acid, and add some barytic water to the remainder if necessary: filter off the folution from the fulphat of barytes, which will have precipitated, and fet it by to crystallize for a few days; that the barytes, if any should remain, may be precipitated. If the cryftals now obtained be of a pale yellow colour, and discover no bluish streaks when sprinkled over with muriatic acid, they are fit for use; but if they still discover bluish or green streaks, the solutions and crystallizations must be repeated.

These crystals must be kept in a well-stopped bottle, which to preferve them from the air should be filled with

alcohol, as they are infoluble in it.

Before they are used, the quantity of iron they contain should be ascertained, by heating 100 grains to redness for half an hour in an open crucible: the prusfic acid will be confumed, and the iron will remain in the state of a reddish brown magnetic oxyd, which should be weighed and noted: This oxyd is half the weight of the Prussian blue afforded by the Prussian alkali; its weight must therefore be subtracted from that of me-tallic precipitates formed by this test. Hence the weight of the crystals, in a given quantity of the folution, should be noted, that the quantity employed in precipitation may be known. Care must be taken to continue the calcination till the oxyd of iron becomes brown; for while " it is black it weighs considerably more than it should to

9. Pruffiat of foda and iron. The only discernible difference between this falt and the last is, that it crystalli-

llet. zes differently ||.

10. Prussiat of ammonia and iron. This triple salt of has also been employed as a test; but it is not so easy to obtain it in a state of purity as the other two. was discovered by Macquer, and first recommended by

It forms flat hexangular crystals, foluble in water, and deliquesces in the air. Heat decomposes it like the

xiv. other Prussiats *.

We shall not give any description of the triple salts

is injected, let it be kept at a white heat for half an formed by digesting the alkaline earths on prussiat of Sebats. iron; they are sufficiently known, and are not of any use except as tests; and in that respect they are inserior to that above described. They are all soluble in water, and are most of them capable of crystallizing.

11. Pruffiat of mercury. This falt, which was first Pruffiat of formed by Scheele, is composed of the pruffic acid mercury. combined with the red oxyd of mercury. It may be formed by boiling the red oxyd of mercury with Pruffian blue. It crystallizes in tetraliedral prisms, terminated by quadrangular pyramids, the fides of which correfpond with the angles of the prism.

This falt is capable of combining with sulphuric and muriatic acids, and forming triple falts, which have not yet been examined s.

& Bertbollet.

SECT. XXIV. Of Formats.

THE compounds into which the formic acid enters are called formats. We shall not describe them, as little has been added to the account already given in the Appendix to the article CHEMISTRY in the Encyclopædia.

SECT. XXV. Of Sebats.

THE compounds into which the febacic acid enters are called febats. For our knowledge of this class of falts we are chiefly indebted to the celebrated Crell, who published a differtation on the sebacic acid and its combinations in the Philosophical Transactions for 1780 and 1782.

1. Sebat of potals. This falt is of a white colour. Alkaline fe-Its crystals are quadrangular pyramids, of which two bats. opposite sides are narrower than the others. It has a sharp faline taste like muriat of ammonia, but milder. It is foluble in water, infoluble in alcohol, and does not deliquesce when exposed to the air. Heat decomposes it.

2. Sebat of foda. This falt is white. Its crystals are pyramids, with three or four fides: a very moderate

heat melts them.

3. Sebat of ammonia. This falt in tafte and folubility resembles muriat of ammonia, but it differs from it in not being capable of subliming iron.

4. Sebat of lime. The crystals of this falt are hex-Earthy feagons, terminated by a plane surface: they have a sharp bats. acrid taste; are very soluble in water, but not in alcohol: they do not deliquesce.

5. Sebat of magnefia. A gummy, faline, uncrystal-

lizable mals.

6. Sebat of alumina. A gummy faline mass, which does not crystallize, and has an austere astringent taste.

7. Sebat of iron. Needle-shaped crystals, which de Metallic se

8. Sebat of lead. Needle shaped crystals, very soluble in water.

9. Sebat of tin. A white deliquescent salt.

10 Sebat of copper. This falt is capable of crystallizing, but is very deliquescent.

11. Sebat of antimony. A crystallizable salt, which

does not deliquesce.

12. Sebat of arsenic. Small crystals.

13. Sebat of mercury. A white powder, very difficultly foluble in water.

14. Sebat of gold. Yellow crystals.

15. Sebat of platinum. Brownish yellow crystals. The bombats or compounds which the bombic acid forms are still unknown.

SECT. XXVI. Of Arfinials.

THE compounds formed by the combination of the arsenic acid with bases are called arseniats. This class of falts was first discovered by Macquer; but little accurate was known concerning it till Scheele made known the arfenic acid.

An abstract of Scheele's experiments has been given

in the article CHEMISTRY, Encycl.

To his description of arseniats several additions might be made, but not of sufficient consequence to warrant a repetition of what has been given in that article; and without such a repetition these additions would scarcely be intelligible.

SECT. XXVII. Of Metallic Acid Salts.

IT has been conjectured that all metals may be converted into acids by combining them with a sufficient quantity of oxygen. This conjecture has been verified in a confiderable number of instances. We have seen the arfenic acid, the tungstic acid, the molybdic acid, and the new metallic acid of Vauquelin. Berthollet has discovered that platinum becomes an acid; and the same thing has been ascertained with regard to tin. Even those metallic oxyds which do not possess many of the characters of acids are capable of combining with alkalies and earths, and of forming peculiar neutral falts. These oxyds, therefore, perform the office of acids; and confequently must be considered as partaking of their nature, or rather as a kind of intermediate substances between acids and those bodies which unite only with acids.

Some of these neutral salts we shall proceed to enu-

merate.

849

Fulmina-

1. Aurat of ammonia, or fulminating gold. This falt is composed of the oxyd of gold and ammonia. ting gold. This compound may be formed by precipitating gold from nitro-muriatic acid by ammonia. The precipitate is fulminating gold. Bergman was the first who clearly demonstrated that this powder is composed of oxyd of gold and ammonia. When heated a little above the boiling temperature it explodes with aftonishing violence. Chemists had made many attempts to explain the cause of this phenomenon, but without fuccefs, till Mr Berthollet discovered the composition of ammonia. After making that discovery, he proved, by a number of delicate and hazardous experiments, that during the fulmination the ammonia is decomposed, that its hydrogen combines with the oxygen of the oxyd and forms water, while the azot flies off in a gaseous form, and occasions

850 . Fulmina-

2. Argentat of ammonia, or fulminating filver. This ting filver. fubstance was discovered by Mr Berthollet. It may be formed by diffolving oxyd of filver in ammonia. It is a black powder. It possesses the fulminating property much more powerfully than the last described substance. The slightest friction makes it explode with This property, as Mr Berthollet has proved ¶, is owing to the same decomposition of ammonia and formation of water that causes the explosion of fulminating

> If a fmall retort be filled with the liquor from which the fulminating filver has been precipitated, and be made to boil, some azot is disengaged, and small opaque crystals are formed confifting of the same substance; which explode when touched, though they be covered with wa

ter. Nitrat and muriat of barytes precipitate filver from Hydro

3. Mercuriat of lime. Oxyd of mercury boiled with lime-water forms, by evaporation, fmall transparent yel- Merce low crystals 1.

4. Mercuriat of ammonia. Oxyd of mercury dif. of ann folves in ammonia in large quantity, and by evaporation $\lim_{\stackrel{\cdot}{\downarrow}} L_{ij}$ furnishes a white falt +.

5. Cuprat of ammonia. Oxyd of copper diffolves inibid. ammonia. Mr Sage has described its crystallization. St It is decomposed by lime and potals, and cuprat of lime amnor and potals are formed.

6. Stannat of gold. When gold is precipitated by Stanna tin it unites with it. Vogel and Beaumé first observed gold. that the precipitate, which is purple, contained tin.

7. Plumbat of lime. Lime-water boiled on the red Piunib oxyd of lead dissolved it. This folution evaporated in of lime a retort, gave very fmall transparent crystals, forming prifinatic colours, and not more foluble in water than lime. It is decomposed by all the fulphats of alkalies and by sulphurated hydrogen gas. The sulphuric and muriatic acids precipitate the lead. It blackens wool, the nails, the hair, white of eggs; but it does not affect the colour of filk, the skin, the yoke of egg, nor animal oil. It is the lead which is precipitated on these coloured substances in the state of oxyd: for all acids can diffolve it. The simple mixture of lime and oxyd * Ben of lead blackens these substances; a proof that the salt Ann. is easily formed *.

8. Zincat of ammonia. De Caffone has published a Zinca great number of experiments on the property which ammo ammonia has of diffolving oxyd of zinc. Lime water 14.11 and potals also dissolve it +.

9. Antimoniat of potals. When antimony is detona-Antimo ted with nitre in a crucible, part of its oxyd unites with of pot the potals of the nitre !.

CHAP. III. Of HYDROSULPHURETS.

SULPHURATED hydrogen gas, which has been deferi- Proper bed in the first part of this article, possesses almost all of simple the properties of acids. It combines with water, and rated in the folution gives a red colour to watership him. It drogen the folution gives a red colour to vegetable blues. It decomposes soaps and sulphurets, and is capable of combining with alkalies, earths, and metallic oxyds, and of forming compounds, to which Mr Berthollet, to whom we are indebted for discovering them, has given the name of hydrofulphurets *.

Before giving any account of these compounds, which Chim II we shall do from the paper of Berthollet just quoted,233. we beg leave to make a few previous observations, in order to rectify some inaccuracies into which we have fallen from not being acquainted with the experiments

of that philosopher.

Sulphur is capable of combining with alkalies, earths, Remarks metals, and metallic oxyds, and forming the compounds on happened and the compounds of the compounds of the compounds on happened and the compounds of the compound of the compound of the compounds of the compound of the compound of the compound o known by the name of fulphurets. The alkaline, earthy, rets. and even some of the metallic sulphurets, can only exist in a state of dryness: the instant they are moistened with water, a quantity of fulphurated hydrogen gas is formed, which combines with the fulphuret, and forms a new compound. To these triple compounds Mr Berthollet has given the name of hydrogenous fulphurets. All folutions of fulphurets in water are in fact hydrogenous fulphurets. Were it not for the formation and combination of fulphurated hydrogen, the alkaline fulphurets

Fiydroful-

phurets.

ful would be completely decomposed by water, and their ts. fulphur precipitated; for water has a stronger affinity for the alkalies than fulphur has. This Berthollet proved by the following experiment: 'To a folution of fulphuret of potafs in water (that is, to hydrogenous fulphuret of potafs), a quantity of oxy muriatic acid fuperfaturated with potafs was added, and the fulphur was immediately precipitated. In this experiment the fulphurated hydrogen was destroyed by the oxygen of the oxy-muriatic acid; and the precipitation of the fulphur shews that its affinity for potals was not sufficient to keep it diffolved, or, which is the same thing, that its affinity for potafs was inferior to that of water.

The fubftance which we described in Part I. chap. iii. fect. 4. of this article, under the name of Black Sulphuret of Mercury, is a hydrogenous fulphuret of mercury, and therefore differs from the red fulphuret of mercury or cinnabar by containing a quantity of ful-phurated hydrogen. Potals has a stronger affaity for this last substance than the sulphuret; potass therefore, by the affiftance of heat, deprives the black or hydrogenous fulphuret of its fulphurated hydrogen, and reduces it to the state of red sulphuret. This explains the method of forming cinnabar described in the section above referred to, and points out a much easier process

for obtaining that ufeful pigment.

We shall now proceed to the method of forming the hydrofulphurets. Berthollet obtained fulphurated hydregen gas from sulphuret of iron in the usual manner, by means of fulphuric acid. It was made to pass thro' a veffel tilled with water before it entered that in which the combination was to take place. By this method a folution of potals was impregnated with fulphurated hydrogen; and in order to be certain of faturating the alkali completely, the gas was added in excess, and the excess was afterwards driven off by means of heat By this method hydrofulphurets of potafs, foda, and ammonia, may be formed.

In order to form hydrofulphuret of lime, that earth was mixed with diffilled water, and fulphurated hydrogen gas passed into this mixture till a sufficient quantity of hydrofulphmet was judged to be formed; the liquid, which contained it in folution, was poured off the undiffolved lime, and faturated to excess with fulphurated hydrogen, and this excess was afterwards driven off

by means of heat.

Hydrofulphuret of magnetia may be formed by diffolving magnetia in water impregnated with fulphura-

ted hydrogen gas.

If a folution of fulphuret of barytes in water, or, more properly, if hydrogenous fulphuret of barytes be evaporated, a great number of confused crystals are formed; if these be separated quickly by filtration, and placed upon blotting paper to dry, a white crystalline fubstance is obtained, which is hydrofulphuret of ba-

The affinities of the alkalies and earths for fulphurated hydrogen appear from the experiments of Berthol-

let to be as follows:

tics

phu-

Barytes, Potafs, Soda, Lime, Ammonia, Magnefia, Targonia.

Almost all the metallic oxyds have a stronger affinity for fulphurated hydrogen than the earths have.

When the hydrofulphusets are prepared with the ne. Properties ceffary precautions to prevent the contact of atmosphe-of hydrorical air, they are colourless, but the action of the air sulphurets. renders them yellow.

If they be decomposed while they are colourless, by pouring upon them sulphuric acid, muriatic acid, or any other acid which does not act upon hydrogen, the fulphurated hydrogen gas exhales without the deposition of a fingle particle of fulphur; but if the hydrofulphuret has become yellow, some sulphur is always deposited during its decomposition, and the quantity of sulphur is

proportional to the deepness of the colour.

The yellow colour, therefore, which hydrofulphurets acquire by exposure to the atmosphere is owing to a commencement of decomposition. Part of the hydrogen of the sulphurated hydrogen abandons the sulphur, combines with the oxygen of the atmosphere, and forms water By degrees, however, a portion of the fulphur is also converted into an acid; and when the proportion of sulphurated hydrogen is diminished, and that of the fulphur increased to a certain point, the fulphur and the hydrogen combine equally with oxygen.

It fulphuric or muriatic acids he poured upon a hydrofulphuret after it has been for fome time exposed to the air, a quantity of fulphurated hydrogen gas exhales, sulphur is deposited, and after an interval of time sulphurous acid is difengaged. It is therefore sulphurous, and not suiphuric acid, which is formed while the hydrofulphuret fpontaneously absorbs oxygen. This acid, however, is not perceptible till after a certain interval of time when feparated from the hydrofulphuret by means of an acid; because as long as it meets with sulphurated hydrogen a reciprocal decomposition takes place. The oxygen of the acid combines with the hydrogen of the gas, and the fulphur of both is precipi-

Sulphurated hydrogen is capable of combining with Meralline feveral of the metals, mercury, for inftance, and filver hydroful-it combines with the greater number of the metallic ox yds, and forms hydrofulphurets, on which the alkalies have no action at the temperature of the atmosphere; But concentrated acids combine with the oxyds of thefe hydrofulphurets, and separate the sulphurated hydrogen

In the greater number of these metallic oxyd hydrofulphurets, the tendency which oxygen and hydrogen have to combine occasions a partial decomposition of the fulphurated hydrogen, and brings the oxyds nearer to the metallic state. In some of these hydrosulphurets part of the fulphur also combines with oxygen, and

torms fulphuric acid.

in the form of gas.

The alkaline hydrofulphurets precipitate all the metals from their combination with acids; they are therefore very valuable tests of the presence of metals in any folution, as they do not precipitate any of the earths except alumina and jargonia. The following table exhibits a view of the effect of hydrofulphuret of potafs, hydrogenous fulphuret of potals, and water impregnated with fulphurated hydrogen gas, upon various metallic folutions.

CHAP. IV. Of CRYSTALLIZATION.

THE word crystal in its strict and proper sense signifies a transparent body possessed of a regular figure. But it is now used to denote a body which has assumed a regular figure whether it be transparent or not. Cryflallization is the all by which this regular figure is formed.

As the greater number of crystals belong to the class of neutral falts, it may not be improper before we conclude this part of the article to make a few observations

on the phenomena of crystallization.

As cryftallization is confessedly nothing else than the regular arrangement of the particles of bodies, it is evident that before it can take place the particles of the body to be crystallized must be at some distance from each other, and that they must be at liberty to obey the laws of attraction. They may be put into this fituation by three methods, folution, suspension, and fusion.

1. Solution is the common method of crystallizing They are diffolved in water: The water is flowly evaporated, the faline particles gradually approach each other, combine together, and form small crystals; which become constantly larger by the addition of other particles till at last they fall by their gravity to the bottom of the vessel. It ought to be remarked, however, that there are two kinds of folution, each of which presents different phenomena of crystallization. Some falts dissolve in very small proportions in cold water, but are very foluble in hot water; that is to fay, water at the common temperature has little effect upon them, but water combined with caloric diffolves them readily. When hot water faturated with any of these falts cools, it becomes incapable of holding them in folution: the consequence of which is, that the faline particles gradually approach each other and crystallize. Sulphat of foda is a falt of this kind. To crystallize such falts nothing more is necessary than to saturate hot water with them, and fet it by to cool. But were we to attempt to crystallize them by evaporating the hot water, we should not succeed; nothing would be procured but Many of the falts which follow this a shapeless mass law of crystallization combine with a great deal of water; or, which is the fame thing, many crystals formed in this manner contain a great deal of water of crystallization.

There are other falts again which are nearly equally foluble in hot and cold water; common falt for instance. It is evident that such salts cannot be crystallized by cool-

ing; but they crystallize very well by evaporating their folution while hot. Thefe falts generally contain but little water of crystallization.

2. It appears, too, that some substances are capable Suspension, of affuming a crystalline form merely by having their particles suspended in water, without any regular solution; at least it is not easy, on any other supposition, to explain the crystallizations of carbonat of lime sometimes deposited by waters that run over quantities of that mineral.

3. There are many fubstances, however, neither folu- And feble in water, nor capable of being fo minutely divided from. as to continue long suspended in that fluid; and which, notwithstanding, are capable of affuming a crystalline form. This is the case with the metals, with glass, and fome other bodies. The method employed to crystallize them is fusion, which is a folution by means of ca-By this method the particles are separated from one another; and if the cooling goes on gradually, they are at liberty to arrange themselves in regular crystals. There are many substances, however, which it has been hitherto impossible to reduce to a crystalline form, either by these or any other method. Whether this be owing to the nature of these bodies themselves, or to our ignorance of the laws by which crystals are formed, as is much more likely, cannot be determined.

The phenomena of crystallization feem to have at-Crystallizatracted but little of the attention of the ancient philoso tion exphers. Their theory indeed, that the elements of bo-plained. dies posses certain regular geometrical sigures, may have been fuggested by these phenomena; but we are ignorant of their having made any regular attempt to explain them. The schoolmen ascribed the regular figure of crystals to their substantial forms, without giving themselves much trouble about explaining the meaning of the term. This notion was attacked by Boyle; who proved, that cryftals were formed by the mere aggregation of particles +. But it still remained to explain, + Treatife on why that aggregation took place? and why the parti-the Origin of cles united in such a manner as to form regular figures? Forms and These questions were answered by Newton Accord-Qualities. ing to him, the aggregation is produced by the attraction which he had proved to exist between the particles of all bodies, and which acts as foon as thefe particles are brought within a certain distance of each other by the evaporation of the liquid in which they are diffolved. The regularity of their figures he explained by supposing, that while in a state of solution they were arranged in the liquid in regular rank and file; the con-

lequence.

Crystalliza fequence of which, as they are acted upon by a power which at equal diffances is equal, at unequal diffances unequal, will be cryftals of determinate figures ‡. + Optics, P.363.

This explanation, which is worthy of Newton, is now univerfally admitted as the true one, and has contributed much towards elucidating this important part of chemistry.

Still, however, there remain various phenomena relating to crystallization which it is no easy matter to ex-

859 Salts do not eatily crystallize in close veffels,

It has been observed, that those saits which crystal. lize upon cooling, do not assume a crystalline form so readily if they are allowed to cool in close vessels. If a faturated folution of fulpliat of foda, for instance, in hot water be put into a phial, corked up closely, and allowed to cool without being moved, no crystals are formed at all; but the moment the glass is opened, the falt crystallizes with such rapidity that the whole of the folution in a manner becomes folid. This phenomenon has been explained by supposing, that there is an affinity between the falt and caloric, and that while the caloric continues combined with it the falt does not cryfallize; that the caloric does not leave the falt fo readily when external air is not admitted, as glass receives it very flowly and parts with it very flowly. In short, the atmospherical air feems to be the agent employed to carry off the caloric; a talk for which it is remarkably well fitted, on account of the change of denfity which it undergoes by every addition of calo-This is confirmed by the quantity of caloric which always makes its appearance during thefe fudden eryftallizations. This explanation might be put to the test of experiment, by putting two solutions of fulphat of foda in hot water in two fimilar veffels; one of glass, the other of metal, and both closed in the fame manner. If the falt contained in the metallic veffel crystallized, which ought to be the case on account of the great conducting power of metals, while that in the glass vessel remained liquid, this would be a confirmation of the theory, amounting almost to demonstration. On the contrary, if both folutions remained liquid, it would be a proof that the phenomenon was still incompletely understood.

Not only falts but water itself, which commonly crystallizes at 32', may be made to exhibit the same phenomenon: it may be cooled much lower than 32 withont freezing. This, as Dr Black has completely proved, depends entirely upon the retention of ealoric.

871 Variety of forms is cryttals accounted for.

If the regular form of crystals depends upon the aggregation of particles, and if during all crystallizations this aggregation goes on in the same manner, why have not all crystals the same form? Some have ascribed these differences to a certain polarity which the particles of bodies are supposed to possess, and which disposes each kind of particles to arrange themselves according to a certain law. Sir Isaac Newton appears rather to have ascribed if to the forms of the particles themaggregation must produce crystals of various shapes; Crystall and therefore their polarity, which is merely a supposition founded on this difference in the appearance of crystals, cannot be admitted. Suppose, for instance, that eight cubic particles were regularly arranged in water, and that by the gradual evaporation of the liquid were to approach, and at last to combine, it is evident that the crystal which they would produce would be a cube. Eight fix-sided prisms would also produce a fix-fided prism: and eight tetrahedrons would form a very different figure.

But it will be asked, if the figure of crystals depends entirely upon the form of the particles that compole them, how comes it that the same substance does not always crystallize in the same way, but presents often such a variety of forms that it is scarcely possible to reckon them? We answer, that these various forms are sometimes owing to variations in the ingredients which compose the integrant particles of any particular body. Alum, for instance, crystallizes in octahedrons; but when a quantity of alumina is added, it crystallizes in cubes; and when there is an excels of alumina it does not crystallize at all. If the proportion of alumina varies between that which produces octahedrons and what produces cubic crystals, the crystals become figures with fourteen fides; fix of which are parallel to those of the cube and eight to those of the octahedron; and according as the proportions approach nearer to those which form cubes or octahedrons, the crystals assume more or less of the form of cubes or octahedrons. What is still more, if a cubic crystal of alum be put into a folution that would afford octahedral crystals, it passes into an octahedron: and on the other hand, an octahedral crystal put into a solution that would afford cubic crystals, becomes itself a cube . Now, how difficult I Le Bla a matter it is to proportion the different ingredients Ann. of with absolute exactness must appear evident to all.

Another circumstance which contributes much to vary the form of cryttals, is the different degree of concertration to which their folution has been reduced, and the rapidity or flowness with which they are formed. For it is too evident to require illustration, that when crystals are deposited very rapidly they must obstruct one another, and mix together fo as very much to obfeure the natural regularity of their form. .

Even the nature of the vessel in which the crystallization is performed is not without fome influence

But, independent of these accidental circumstances, Hany'st Mr Hauy has shewn that every particular species of ory of on crystals has a primitive figure, and that the variations stals. are owing to the different ways in which the particles arrange themselves. Of this theory, which is certainly exceedingly ingenious, and even fatisfactory, we shall attempt to give a short view.

Happening to take up a hexangular prism of calcareous spar, or carbonat of lime, which had been detached from a group of the fame kind of crystals, he observed felves ‡; and this feems to be the real folution of the that a small portion of the crystal was wanting, and that problem. For supposing that all particles have the the fracture presented a very smooth surface. Let abede fame form, they must of course possess the same polari- fgh (fig. 8.) be the crystal; the fracture lay obliquely as ty; and therefore every crystal must have the same form. the trapezium psut, and made an angle of 135°, both It is impossible, then, to account for the different forms with the remainder of the bale abes ph and with tuef, the of crystals without supposing that the particles which remainder of the side inef. Observing that the segment compose them have also different forms. And if the psutin thus cut off had for its vertex in, one of the edges particles of bodies have different forms, their regular of the base abenih of the prism, he attempted to detach

\$ Optics, P- 375

a-a fimilar fegment in the part to which the next edge. en belonged, employed for that purpose the blade of a knife, directed in the fame degree of obliquity as the trapezium psut, and affisted by the strokes of a hammer. He could not succeed: But upon making the attempt upon the next edge bc, he detached another fegment, precifely fimilar to the first, and which had for its vertex the edge bc. He could produce no effect on the next edge ab; but from the next following, ah, he cut a fegment similar to the other two. The fixth edge likewise proved refractory. He then went to the other base of the prism defghr, and found, that the edges which admitted fections fimilar to the preceding ones were not the edges ef, dr, gk, corresponding with those which had been found divisible at the oppolite base, but the intermediate edges de, k r, gf. The trapezium l q y v represents the section of the segment, which had kr for its vertex. I'his fection was evidently parallel to the section p sut; and the other four sections were also parallel two and two. These sections were, without doubt, the natural joinings of the layers of the crystal: And he easily succeeded in making others parallel to them, without its being possible for him to divide the crystal in any other direction. In this manner he detached layer after layer, approaching always nearer and nearer the axis of the prilm, till at last the bases disappeared altogether, and the prism was converted into a folid OX (fig. 9.), terminated by twelve pentagons, parallel two and two; of which those at the extremities, that is to fay, ASRIO, IG EDO, BAODC at one end, and FKNPQ, MNPXU, ZQPXY at the other, were the results of mechanical division, and had their common vertices O, P situated at the centre of the bases of the original prism. The fix lateral pentagons RSUXY, ZYRIG, &c. were the remains of the fix sides of the original prism.

By continuing fections parallel to the former ones, the lateral pentagons deminished in length; and at last the points R, G coinciding with the points Y, Z, the points S, R with the points U, Y, &c. there remained nothing of the lateral pentagons but the triangles YIZ, UXY, &c. (fig. 10.). By continuing the same sections, these triangles at last disappeared, and the prism was converted into the rhomboid a e (fig. 11.).

So unexpected a refult induced him to make the fame attempt upon more of these crystals; and he found that all of them could be reduced to similar rhomboids. He found also, that the crystals of other substances could be reduced in the same manner to certain primitive forms; always the same in the same substances, but every substance having its own peculiar form. The primitive form of sluat of lime, for instance, was an octahedron; of sulphat of barytes, a prism with rhomboidal bases; of field spath, an oblique angled parallelopiped, but not rhomboidal; of adamantine spar, a rhomboid, somewhat acute; of blende, a dodecahedron, with rhomboidal sides; and so on.

These must be considered as the real primitive forms of the crystals; the other forms which they often assume may be called secondary forms.

The primitive crystals obtained by the above process may be divided by sections parallel to their different sides: all the matter which surrounded this primitive crystal

SUPPL. VOL. I. Part I.

may also be divided by sections parallel to the sides of Crystallizathe primitive crystal. It follows from this, that the parts detached by means of these sections are similar, and differ from one another only in fize, which diminifhes in proportion to the length that the division is carried. But the division of the cryttals into similar solids has a term, beyond which we should come to the smallest particles of the body, which could not be divided without chemical decomposition. It is probable, therefore, that the form of the integrant particles of a body is the fame with the primitive form of its crystals. Here, then, we have a method of discovering the form of the particles of bodies; and if this method could be applied to all substances whatever, it would enable us to ascertain the affinity of all bodies for each other by accurate calculation. It must be allowed, that several objections might be made to the conclusions of Mr Hany; but his theory is, on the whole, fo plaufible, that it would certainly be worth while to extend it, and apply it to the calculation of affinities as far as it is susceptible of the application. If the crystals obtained by the above process be the primitive forms, it becomes a question of some consequence to determine in what manner the secondary forms are produced.

According to Hauy, all the parts superadded to the primitive crystals, in order to form the secondary crystal, consist of plates, which decrease regularly by the subtraction of one or more rows of integrant particles, in such a manner, that the number of these ranks, and consequently the form of the secondary crystal, may be

determined by theory (c).

To explain this, let us suppose that EP (fig. 12.) represents a dodecahedron, terminated by equal and similar rhombs; that this dodecahedron is a secondary crystal, the primitive form of which is a cube: the situation of this cube in the dodecahedron may be conceived from fig. 13. 'I'he smaller diagonals DC, CG, GF, FD, of four sides of the dodecahedron, united round the same solid angle L, form the square CDFG. Now there are six solid angles, composed of sour plains, towit, the angles L, O, E, N, R, P (fig. 12.); and consequently, by making sections through the smaller diagonals of the sides that form these angles, six squares will be made apparent, which are the six sides of the primitive cube, three of which are represented in fig. 13. CDFG, ABCD, BCGH.

This cube being composed of cubic integrant particles, each of the pyramids, LCDFG for instance (fig. 13.) which repose upon its sides, must also, according to the theory, be composed of similar cubic particles. To make this appear, let us suppose that ABFG (fig. 14.) is a cube composed of 729 small cubes: Each of its sides will consist of 81 squares, being the external fides of as many cubic particles, which together constitute the cube. Upon ABCD, one of the sides of this cube, let us apply a square lamina, composed of cubes equal to those of which the primitive crystal confifts, but which has on each fide a row of cubes less than the outermost layer of the primitive cube. It will of course be composed of 49 cubes, 7 on each side; so that its lower base on fg (fig. 15.) will fall exactly on the square marked with the same letters in fig. 14.

Above this lamina let us apply a fecond lmpu (fig. 3 D 16.),

Crystalliza 16.), composed of 25 cubes; it will be situated exactly contiguous to AD and BC, two triangles. Let us Crystalliza above the square marked with the same letters (fig. 14.). Upon this fecond let us apply a third lamina vxyz (fig. 17.), confifting only of 9 cubes; fo that its base shall rest upon the letters v x y z (fig. 14.). Laftly, on the middle square r let us place the small cube r (fig. 18.), which will represent the last lamina.

It is evident, that by this process a quadrangular pyramid has been formed upon the face ABCD (fig. 14.), the base of which is this face, and the vertex the cube r (fig. 18.). By continuing the fame operation on the other five fides of the cube, as many fimilar pyramids will be formed; which will envelope the cube on every fide.

It is evident, however, that the fides of these pyramids will not form continued planes, but that, owing to the gradual diminution of the laminæ of the cubes which compose them, these sides will resemble the steps of a ftair. We can suppose, however (what must certainly be the case), that the cubes of which the nucleus is formed are exceedingly small, almost imperceptible; that therefore a vast number of laminæ are required to form the pyramids, and consequently that the channels which they form are imperceptible. Now DCBE (fig. 19.) being the pyramid resting upon the face ABCD (fig. 14.), and CBOG (fig. 19.) the pyramid applied to the next face BCGH (fig. 14.), if we confider that every thing is uniform from E to O (fig. 19.) in the manner in which the edges of the lamina of superposition (as the Abbé Hauy calls the laminæ which compose the pyramids) mutually project beyond each other, it will readily be conceived, that the face CEB of the first pyramid ought to be exactly in the same plane with the face COB of the adjacent pyramid; and that therefore the two faces together will form one rhomb ECOB. But all the fides of the fix pyramids amount to 24 triangles fimilar to CEB; consequently they will form 12 rhombs, and the figure of the whole crystal will be a dodecahedron, fimilar to that represented in fig. 12. and 13.

If the decrease of the laminæ of fuperposition took place according to a more rapid law, if each lamina had on its circumference two, three, or four rows of cubes less than the inferior lamina-in that case, the pyramids produced being lower, their adjacent faces would no longer form one plane; and therefore the furface of the fecondary crystal would confist of 24 ifofceles triangles, all inclined towards each other.

In this manner Mr Hauy has shewn, that a variety of secondary crystals are formed, and that their forms vary by means of flight variations in the ratio of the decrement. Dodecahedral sulphuret of iron, for instance, is formed from a cubic nucleus, by the addition of laminæ, decreasing, as in the example given above, with this difference, that from every lamina laid upon the face ABCD (fig. 14.) only one row of cubes are subtracted at the fides AD and BC respectively; whereas two rows are subtracted at each of the fides AB and CD. The consequence of this more rapid decrement on two parallel fides than on the other two will be, that the pyramid raised on the face ABCD (fig. 14.), instead of terminating in a single cube as in the example given above, will terminate in a range of cubes; or (supposing the cubes infinitely small) instead of terminating in a point, it will terminate in a ridge. The pyramid will therefore have for its two sides, contigufuppose also, that with regard to the laminæ of superposition which arise on the face BCGH (fig. 14), the decrements follow the fame law, and that each lamina decreafes by two rows of cubes towards the lines BC and HG, and only by one row towards the lines CG, BH: The pyramid, in that case, will be placed in a direction opposite to the pyramid on ABCD, the ridge at the vertex of it running parallel to BC: the vertex of the pyramid raifed upon CDFG must be parallel to CG: the pyramids on the three other fides of the cube ought to stand each like that which arises on the opposite face

The fides of all the fix pyramids thus formed amount to twelve trapeziums and twelve triangles. Every triangle is evidently contiguous and in the fame plane with a trapezium of the nearest pyramid; consequently the secondary crystal thus formed consists of twelve fides, each of which is a pentagon.

Several other examples have been given by Mr Hauy; but these are sufficient to shew in what manner the various secondary forms of crystals are constructed, according to the theory of that ingenious philosopher.

In his refearches on this subject, Mr Hauy perceived, that some crystals assumed secondary forms which could not be accounted for by any decrement whatever along the edges. Thus, for inftance, fome bodies, the primary form of which is cubic, are sometimes found crystallized in regular octagons. Mr Hauy explains the formation of these secondary crystals, by supposing that the decrement took place parallel, not to the edges, but to the diagonals of the faces of the primary cubes.

In order to comprehend this, let us suppose ABCD (fig. 20.) to be the surface of a lamina composed of fmall cubes, the bases of which are represented by the little squares in the figure. It is evident, that the cubes a, b, c, d, e, f, g, b, i, are in the direction of the diagonal of the square ABCD; that the row of cubes q, v, k, u, x, y, z, is parallel to the diagonal; as also the row n, t, l, m, p, o, r, s; and that the whole figure might be divided into rows of squares, each of which would be parallel either to the diagonal AC or DB.

Now we may conceive that the laminæ of superpofition, instead of decreasing by rows of cubes parallel to the edges AB, AD, decrease by rows parallel to the

Let it be proposed to construct around the cube AB GF (fig. 21.), confidered as a nucleus, a secondary solid, in which the laminæ of superposition shall decrease on all fides by fingle rows of cubes, but in a direction parallel to the diagonals. Let ABCD (fig. 22.), the superior base of the nucleus, be divided into 81 squares, representing the faces of the small cubes of which it is composed. Figure 23. represents the superior surface of the first lamina of superposition; which must be placed above ABCD (fig. 22.), in fuch a manner that the points a, b', c', d', (fig. 23.) answer to the points a, b, c, d, (fig. 22.). By this disposition the squares A a, B b, C c, D d (fig. 22.), which compose the four outermost rows of squares parallel to the diagonals AC, BD, remain uncovered. It is evident also, that the borders QV, ON, IL, GF (fig. 23.), project by one range beyond the borders AB, AD, CD, BC (fig. 22.), which is necessary, that the nucleus may be enveous to AB and DC, two trapeziums, and for its fides, loped towards these edges: For if this were not the

cale, re-entering angles would be formed towards the parts AB, BC, CD, DA, of the crystal; which angles appear to be excluded by the laws which determine the formation of simple crystals, or, which comes to the same thing, no such angles are ever observed in any crystal. The solid must increase, then, in those parts to which the decrement does not extend. But as this decrement is alone sufficient to determine the form of the secondary crystal, we may set aside all the other variations which intervene only in a subsidiary manner, except when it is wished, as in the present case, to construct artificially a solid representation of a crystal, and to exhibit all the details which relate to its structure.

The fuperior face of the fecond lamina will be A' G'L'K' (fig 24.) It must be placed so that the points a'', b'', c'', d'', correspond to the points a'b'c'd'' (fig. 23.), which will leave uncovered a fecond row of cubes at each angle, parallel to the diagonals AC and BD The folid still increases towards the sides. The large faces of the laminæ of superposition, which in fig. 23. were octagons, in fig. 24. arrive at that of a square; and when they pass that term they decrease on all fides; fo that the next lamina has for its superior face the square B'M'L'S' (fig. 25.), less by one range in every direction than the preceding lamina (fig. 24.). This square must be placed so that the points e', f', g', h', (fig. 25.) correspond to the points e, f, g, h (fig. 24.). Figures 26, 27, 28, and 29, represent the four laminæ which ought to rife fuccessively above the preceding; the manner of placing them being pointed out by corresponding letters, as was done with respect to the three first laminæ. The latt lamina z'(fig. 30.) is a single cube, which ought to be placed upon the square z (fig. 29.).

The laminæ of superposition, thus applied upon the side ABCD (fig. 22.), evidently produce four saces, which correspond to the points A, B, C, D, and form a pyramid. These faces, having been formed by laminæ, which began by increasing, and afterwards decreased, must be quadrilaterals of the sigure represented in sig. 31.; in which the inserior angle C is the same point with the angle C of the nucleus (fig. 21. and 22.); and the diagonal LQ represents L'G' of the lamina A'G'L'K' (fig. 24). And as the number of laminæ composing the triangle L Q C (fig. 31.) is much smaller than that of the laminæ forming the triangle ZLQ, it is evident that the latter triangle will have a

much greater height than the former.

The furface, then, of the fecondary cryftal thus produced, must evidently consist of 24 quadrilaterals (for pyramids are raised on the other 5 sides of the primary cube exactly in the same manner), disposed 3 and 3 around each solid angle of the nucleus. But in consequence of the decrement by one range, the three quadrilaterals which belong to each solid angle, as C (fig. 21.) will be in the same plane, and will form an equilateral triangle Z1N (fig. 32.). The 24 quadrilaterals, then, will produce 8 equilateral triangles; and consequently the secondary crystal will be a regular octagon. This is the structure of the octahedral sulphuret of lead and of muriat of soda.

Decrements which take place in this manner have been called by Mr Hauy decrements on the angles,

There are certain cryftals in which the decrements on the angles do not take place in lines parallel to the diagonals, but parallel to lines fituated between the diagonals and the edges. This is the case when the sub-Crystallizatractions are made by ranges of double, triple, &c. moleculæ. Fig. 33. exhibits an instance of the sub-tractions in question; and it is seen that the moleculæ which compose the range represented by that sigure are afforted in such a manner as if of two there were formed only one; so that we need only to conceive the crystal composed of parallelopipedons having their bases equal to the small rectangles a b c d, e d f g, b g i l, &c. to reduce this case under that of the common decrements on the angles. To this particular kind of decrement Mr Hauy has given the name of intermediate.

In other cryftals the decrements, either on the edges or on the angles, vary according to laws, the proportion of which cannot be expressed but by the fraction $\frac{2}{3}$ or $\frac{3}{4}$. It may happen, for example, that each lamina exceeds the following by two ranges parallel to the edges, and that it may at the same time have an altitude triple that of a simple molecule. Figure 34. represents a vertical geometrical section of one of the kinds of pyramids which would result from this decrement; the effect of which may be readily conceived, by considering that AB is a horizontal line taken on the upper base of the nucleus, b a $\approx r$ the section of the first lamina of superposition, g f e n that of the second, &c. These decrements Mr Hauy has called mixed.

These two last species of decrements occur but rarely; Mr Hauy found them only in certain metallic substances.

All the metamorphoses to which crystals are subjected depend, according to Mr Hauy, on the laws of structure just explained, and others of the like kind. Sometimes the decrements take place at the same time on all the edges; as in the dodecahedron having rhombuses for its planes, as before mentioned; or on all the angles, as in the octahedron originating from a cube. Sometimes they take place only on certain edges or certain angles. Sometimes there is an uniformity between them; fo that it is one fingle law by one, two, three ranges, &c. which acts on the different edges, or the different angles. Sometimes the law varies from one edge to the other, or from one angle to the other; and this happens above all when the nucleus has not a fymmetrical form; for example, when it is a parallelopipedon, the faces of which differ by their respective inclinations, or by the measure of their angles. In certain cases the decrements on the edges concur with the decrements on the angles to produce the same crystalline form. It happens also sometimes that the fame edge, or the fame angle, is subjected to several laws of decrement that succeed each other. In short, there are cases where the secondary crystal has faces parallel to those of the primitive form, and which combine with the faces produced by the decrements to modify the figure of the crystal.

The crystals arising from a single law of decrement have been called by Mr. Hauy simple secondary forms; these which arise from several simultaneous laws of decrement he has called compound secondary forms.

"If amidit this diverfity of laws (he observes), sometimes infulated, sometimes united by combinations more or less complex, the number of the ranges subtracted were itself extremely variable; for example, were these decrements by twelve, twenty, thirty, or forty ranges, or more, as might absolutely be possible, the multitude

Dd2

Crystalliza. of the forms which might exist in each kind of mineral would be immense, and exceed what could be imagined. But the power which effects the fubtractions feems to have a very limited action. These subtractions, for the most part, take place by one or two ranges of molecules. I have found none which exceeded four ranges, except in a variety of calcareous spar, forming part of the collection of C. Gillet Laumont, the structure of which depends on a decrement by fix ranges; fo that if there exilt laws which exceed the decrements by four ranges, there is reason to believe that they rarely take place in nature. Yet, notwithstanding these narrow limits by which the laws of crystallization are circumscribed. I have found, by confining myfelf to two of the simplest laws, that is to fay, those which produce fubtractions by one or two ranges, that calcareous spar is fusceptible of two thoufand and forty-four different forms: a number which exceeds more than fifty times that of the forms already known; and if we admit into the combination decrements by three and four ranges, calculation will give 8,388,604 possible forms in regard to the same substance. This number may be still very much augmented in confequence of decrements either mixed or intermediary.

"The striæ remarked on the surface of a multitude of crystals afford a new proof in favour of theory, as they always have directions parallel to the projecting edges of the laminæ of fuperposition, which mutually go beyond each other, unless they arise from some particular want of regularity. Not that the inequalities refulting from the decrements must be always sensible, fuppofing the form of the crystals had always that degree of finishing of which it is fusceptible; for, on account of the extreme minuteness of the molecules, the furface would appear of a beautiful polish, and the striæ would elude our fenfes. There are therefore fecondary crystals where they are not at all observed, while they are very visible in other crystals of the same nature and form. In the latter cafe, the action of the causes which produce crystallization not having fully enjoyed all the conditions necessary for perfecting that so delicate operation of nature, there have been flarts and interruptions in their progrefs, fo that, the law of continuity not having been exactly observed, there have remained on the furface of the crystal vacancies apparent to our eyes. Thefe small deviations are attended with this advantage, that they point out the direction according to which the firize are arranged in lines on the perfect forms where they escape our organs, and thus contribute to unfold to us the real mechanism of the structure.

"The fmall vacuities which the edges of the laminæ of superposition leave on the surface of even the most perfect lecondary crystals, by their re-entering and falient angles, thus afford a fatisfactory folution of the difficulty a little before mentioned; which is, that the fragments obtained by division, the external sides of which form part of the faces of the fecondary crystal, are not like those drawn from the interior part. For this diverfity, which is only apparent, arises from the fides in question being composed of a multitude of small planes, really inclined to one another, but which, on account of their smallness, present the appearance of one plane; fo that if the division could reach its utmost bounds, all these fragments would be resolved into molecules fimilar to each other, and to those fituated towards the centre.

66 The fecundity of the laws on which the variations Crysla of crystalline forms depend, is not confined to the producing of a multitude of very different forms with the fame molecules. It often happens also, that molecules of different figures arrange themselves in such a manner as gives rife to like polyhedra in different kinds of minerals. Thus the dodecahedron with rhombuses for its planes, which we obtained by combining cubic molecules, exists in the granite with a structure composed of small tetrahedra, having isosceles triangular faces; and I have found it in fparry fluor (fluat of lime), where there is also an assemblage of tetrahedra, but regular; that is to fay, the faces of which are equilateral triangles. Nay more, it is possible that similar molecules may produce the same crystalline form by different laws of decrement. In short, calculation has conducted me to another refult, which appeared to me flill more remarkable, which is, that, in consequence of a simple law of decrement, there may exist a crystal which externally has a perfect refemblance to the nucleus, that is to fay, to a folid that does not aide from any law of decrement *." Chim.

Such is a short view of the theory by which Mr 225, Hauy explains the various crystalline forms of the fame fubstance. We would with pleasure have entered more into detail, had not most of his examples been deduced from fubstances which belong rather to mineralogy than to the elements of chemistry. theory, to fay no more of it, is, in point of ingenuity, inferior to few; and the mathematical skill and industry of its author are intitled to the greatest applause.

But what we consider as the most important part of that philosopher's labours, is the method which they point out of discovering the figure of the integrant particles of crystals; because it may pave the way for calculating the affinities of bodies, which is certainly by far the most important part of chemistry. This part of the subject, therefore, deserves to be investigated with

the greatest care.

Mr Hauy has found, that the primitive form of all the crystals which he has examined may be reduced to fix; 1. The parallelopipedon in general, comprehending the cube, the rhomboid, and all folids terminated by fix fides parallel two and two; 2. The regular tetrahedron; 3. The octahedron with triangular fides; 4. The hexagonal prifm; 5. The dodecahedron bounded by rhombs; 6. The dodecahedron bounded by isosceles triangles. Were we to suppose that these primitive forms are exactly fimilar to the form of the integrant particles which compose them, it would follow, that the integrant particles of all the crystals hitherto formed have only fix different forms. This supposition, however, is not probable; because the same nucleus has been discovered in different species of minerals, and becaufe we can eafily conceive integrant particles of different forms combining in fuch a manner as to compole nuclei of the fame figure, just as we have feen that different primitive forms are capable of producing the same fecondary form. Still, therefore, in endeavouring to discover the integrant particles of bodies, there are difficulties to remove, which hitherto, at least, have been unfurmountable. But the theory of Mr Hauy may be confidered as a first step towards the discovery and a step in relearches of fo difficult a nature is of very great confequence.

We have now finished the three first parts of this article, which comprehend all the elementary part of chemistry. We ought now to proceed to the fourth part, which was to confift of a chemical examination of fubstances as they exist in nature in the mineral, vegetable, and animal kingdoms; but this, for various reasons, we shall defer till we come to the words MINERALOGY, and Animal and Vegetable SUBSTANCES.

We shall finish this article with a few remarks upon the chemical nomenclature, which for some time past

has been an object of serious attention.

Chemistry was unfortunately first cultivated by a fet n he che- of ignorant men, filled with the highest notions of their own importance, and buoyed up with the mighty feats which they were to perform by their art. The little which they did know they were anxious to conceal; and their anxiety was no lefs to inspire the world with high ideas of their knowledge and power. The confequence of this was, that they loaded chemistry with the most ridiculous and whimfical names that can well be conceived. Liver of fulphur, mercury of life, borned moon, butter of antimony, the double fecret, the corraline fecret, the fecret of vitriol, the wonderful falt, the fecret falt, the falt with many virtues, the falt of two ingredients, the foliated earth of tartar, were the names by which they diffinguished iome of the most familiar preparations; and, were it worth while, a great many more names of the same stamp might easily be added.

As foon as chemistry had attracted the attention of men of science, the absurdity of its nomenclature was felt, and feveral partial improvements were at different times made in it. Macquer, in particular, discarded many of the ancient names, and substituted others less

exceptionable in their place.

But soon after the publication of the first edition of his Dictionary, an evil began to be felt feverely, which never could have occurred to the earlier chemists. Hitherto the number of objects which had engaged the attention of those who cultivated the science had been very limited; the acids amounted only to five, the earths to four, the metals to 12 or 14, and the neutral falts fearcely exceeded 20 or 30. To remember names for so small a number of bodies, however ridiculous they happened to be, was no very difficult matter. But about that time, in consequence chiefly of the discovery of fixed air by Dr Black, which laid the foundation of pneumatic chemistry, the science began to extend itself, and to enlarge its boundaries with inconceivable rapidity. The number or bodies connected with it, and which it had to describe, soon became immense; and if every one of them received names not dependant upon one another, the most retentive memory could not have remembered the thousandth part of them.

The difficulty of studying chemistry from that time till the year 1782 must have been very great: it was even perceived and complained of by the masters of the science. In 1782 Mr de Morveau, who had undertaken the chemical part of the Encyclopedie Methodique, published in the Journal de Physique a new chemical nomenclature, and at the fame time invited all those perfons who were fond of chemistry, and interested in its progrefs, to propose of jections and improvements.

This new nomenclature was formed agreeably to the

five following rules:

1. Every substance ought to have a name, and not to Corclusion. be denoted by a phrase.

2. Names ought to be as much as possible conformable

to the nature of the things fignified by them.

3. When the character of a substance is not well enough known to determine the denomination, a name which has no meaning is preterable to one which conveys a talfe idea.

4. In the choice of new words, those ought to be preferred which have their roots in the dead languages most generally known, that the word may be easily juggested by the sense, and the sense by the word.

5. The new words ought to be as fuitable as possible to the genius of the languages for which they are formed.

This nomenclature was approved of by Macquer, and by Bergman, who had himfelf proposed one upon a plan not very different (D). He wrote to Morveau, and exhorted him to profecute his undertaking with courage. "Do not spare (says he) a single improper denomination; those that are already learned will be always so, and those that are not will learn the sooner *." d those that are not will learn the sooner ... Method. This nomenclature was adopted by feveral chemists, Chim. Pre-

and it was used in the greatest part of the first volume face. of the chemical part of the Encyclopedie Methodique; but the new discoveries in chemistry had produced a more accurate method of reafoning, and had enabled Lavoisier to explain the phenomena of the science without the affiltance of the hypothetical principle of phlogiston, which had hitherto been necessary. As the language, even in its improved flate, was accommodated to this principle, and presupposed its existence, new changes became evidently necessary, in order that, according to Morveau's rule, the words might denote the most effential properties of the things intended to be fignified. Accordingly, when Morveau was in Paris in 1787, Laweiser, Berthollet, and Fourcroy, agreed to labour in concert with him to bring the chemical nomenclature still nearer to perfection. These philosophers, affifted by the mathematicians of the Royal Academy and by feveral chemits, formed a new nomenclature, which they made public in 1787.

For some time little attention was paid to this no-menclature by foreign chemists, and it seemed generally to be disapproved. The adherents of the phlogistic fystem in France, who were exceedingly numerous, viewed it as an engine artfully formed to undermine and destroy their favourite theory. They resolved, therefore, unanimoufly, to cruth, if possible, this new instru-

ment, which they confidered as

in nostros fabricata machina muros, Inspectura domos, venturaque desuper urbi.

And for this purpose they exerted themselves with a vigour, which was only equalled by the zeal and indefatigable exertions of their antagonists. A kind of civil war was thus kindled in the republic of letters, which was carried on with great animofity: And posterity will fee, with regret, men of undoubted genius at times diverting themselves of the armour of truth and of candour, and endeavouring to serve their party, and stab their adverfaries with darts sleeped in the poison of calumny and falsehood * This contest, however, which * See the was not confined to France, was productive of good ef- Jour. de fects, which infinitely furpaffed all the bad ones. It Phys. for

occa-90, 91, pef-

Conclusion occasioned an accumulation of facts, produced a rigid examination of theories and opinions, introduced an accuracy into chemical experiments which has been of the most effential service, and gave that tone and vigour to the cultivators of chemistry which have brought to light the most sublime and unlooked-for truths. It deserves attention, and the fact is no inconfiderable evidence in favour of the antiphlogistic theory, that almost all the *illustrious chemists who at present adhere to it declared originally against it. Berthollet, Morveau, Black, Kirwan, and many other chemists who are now its ablest defenders, were at first its most powerful opponents. "This fystem had hardly been published in France (fays Dr Priestley, who still continues to adhere to the doctrine of phlogifton) before the principal philosophers and chemists of England, notwithstanding the rivalship which has long fublished between the two countries, eagerly adopted it. Dr Black in Edinburgh, and as far as I hear all the Scots, have declared themselves converts, and, what is more, the fame has been done by Mr Kirwan, who wrote a pretty large treatife in opposition to it. The English reviewers of books, I perceive, univerfally favour the new doctrine. In America, also, I hear of nothing else. It is taught, I believe, in all the schools on this continent, and the old fystem is entirely exploded. And now that Dr Crawford is dead, I hardly know of any person except my friends of the Lunar Society at Birmingham, who adhere to the doctrine of phlogiston; and what may now be the case with them in this age of revolutions, philosophical as well as civil, I will not at this distance answer for.

" It is no doubt time, and of course opportunity of examination and difcussion, that gives stability to any principles. But this new theory has not only kept its ground, but has been constantly and uniformly advancing in reputation more than ten years, which, as the attention of fo many persons, the best judges of every thing relating to the subject, has been unremittingly given to it, is no inconsiderable period. Every year of already arrived at a state of such absolute perfection, that the last twenty or thirty has been of more importance to science, and especially to chemistry, than any ten in

† Considera- the preceding century +."

phlogiston,

Introduc-

gion.

We have endeavoured in the preceding article to flate the different theories which have successively made their appearance in chemistry with as much fairness as possible. If we have succeeded, the reader will be enabled to judge for himself which of these theories is the most confiftent with truth; or rather, if we have fucceeded, he will join with us in thinking that the theory of Lavoifier is in most points an accurate account of what takes place in nature.

This we confider as a fufficient reason for having adopted the new nomenclature; for as Morveau long ago observed, most of the objections that were made to it were rather levelled at the doctrine of those who formed it, than at the nomenclature itself. Its fuperiority to every other nomenclature cannot be difputed for an instant; and the vast facility which it lias

added to the acquisition of chemistry, must be acknow- Jo cluss ledged by every one who knows any thing about the fcience. The table of the new nomenclature will not be expected here, as it has been already given in the Appendix to the article CHEMISTRY in the Encyclopadia. At any rate, it would have been unnecessary, as we have used the new names all along; and therefore our readers must by this time be well acquainted with

Upon the almost infinite number of criticisms which have been made on the new nomenclature, and the many new terms which fince its publication have been fucceffively proposed, we do not mean to enter. Few of these terms can bear a comparison with the French nomenclature, and still fewer have any claim to be preferred to it; and the philosophers who perfift in these useless innovations, are more probably actuated by the defire of appearing to have a share in the great revolution which chemistry has undergone, than by any hopes of being able to improve the accuracy or the elegance of its language. How few have displayed the magnanimity of an illustrious philosopher of our own country, who, though he had invented a new nomenclature himfelf, exhorted his pupils not to use it, but to adopt that of the French chemists, which was likely soon to come into universal use.

Even the etymological remarks which have been made on the new nomenclature, we confider as either of little consequence or as ill-founded. The philosophers who formed it have displayed a fagacity and a moderation which could not be excelled, and have, upon the whole, formed a language much more fystematic, and much more perfect, than could have been expected; and whoever compares it with the nomenclature proposed in 1782 by Morveau, will fee how great a share of it is due to that illustrious and candid philosopher.

Notwithstanding what we have here faid, we would not be understood to confider the new nomenclature as no alferation whatever can be made in it except for the worse. Such perfection belongs not to the works of man; nor if it did, could it be expected in this case, if we confider for a moment the prefent state of chemistry. New discoveries must occasion additions and alterations in the nomenclature; but the authors of the new nomenclature have given us the rules by which changes and additions are to be made; and if they are adhered to, we may expect with confidence that the language of chemistry will in its advancement to perfection keep pace with the science. We have in the preceding article ventured in an instance or two to adopt little improvements that have been fuggested by later writers. We have taken the liberty, too, of choosing, from the variety which the British chemists have proposed, that mode of spelling each of the terms which appeared to us most agreeable to the English idiom, and most conformable to analogy: Whether or not we have made a proper choice must be left for others to determine.

Erratum in the article Chemistry.

In page 257. dele the whole account of Adamanta, the existence of which as a peculiar earth has been destroyed by the subsequent experiment of Klaproih. It may be proper to mention, that in that section, line 28.

CHE

CHERUBIM were emblematical figures; of which an account, a very vague one indeed, has been given in the Encyclopadia Britannica. We are far from thinking ourselves qualified to improve that account, or to explain emblems in the Jewish worship, which even Jofephus did not understand; and we certainly should not have refumed the subject, but to gratify a numerous class of our readers, and to comply with the request of

fome highly respected friends.

The followers of Mr Hutchinson, who are firmly perfuaded that their mafter brought to light from the writings of the Old Testament many important doctrines which had lain concealed from all the piety, all the industry, and all the learning of 1700 years, believe that, among other things, he and they have been able to alcertain the form and the import of the Hebrew Cherubim. Their discoveries on this subject, as we have been told by better judges than we pretend to be, are more clearly stated by Mr Parkhurst in his Hebrew Lexicon, than by any other writer of that school. We shall therefore lay before our readers his doctrine respecting the form of the artificial cherubs, as well as of their emblematical meaning; and fubjoin a few remarks, which the nature of his reasoning has forced from us.

" First, then, as to the form of the artificial cherubs in the tabernacle and temple, Moses (says our author) was commanded (Fxod. xxv. 18, 19.) 'Thou shalt make two cherubs: of beaten gold shalt thou make them at the two ends of the mercy leat. And thou בפראח אדם the likeness as the appearance of a man,

CHE

shalt make one cherub at the one end, and the other Cherubim. cherub at the other end : מן הבפרח, out of the mercyfeat (Margin Eng. Translat. of the matter of the mercy-feat) shall ye make the cherubs at the two ends thereof.' All which was accordingly performed (Exod. xxxvii. 7, 8.), and these cherubs were with the ark placed in the holy of holies of the tabernacle (Exod. xxvi. 33, 34. xl. 20.); as those made by Solomon were afterwards in the holy of holies of the temple (r Kings vii.

We may observe that in Exodus Jehovah speaks to Moses of the cherubs as of figures well known; and no wonder, fince they had always been among believers in the holy tabernacle from the beginning. (See Gen. iii. 24. Wild. ix. 8. And though mention is made of their faces (Exod. xxv. 20. 2 Chron. iii. 13.), and of their wings, (Exod. xxv. 20. 1 Kings viii. 7 2 Chron. iii. 11, 12.); yet neither in Exodus, Kings, nor Chronicles have we any particular description of their form. This is however very exactly, and, as it were, anxiously supplied by the prophet Ezekiel, ch. i. 5. Out of the midst thereof (i. e. of the fire infolding itself, ver. 4.) the likeness of four living creatures or animals; the likeness of a man (being) with them. This last Hebrew expression cannot mean that they, i. e. the four animals, had the likeness of a man, which interpretation would indeed make the prophet contradict himself (comp. ver. 10.); but it imports that the likeness of a man in glory, called (verse 26.)

3 E 2

Cherubim. and particularly described in that and the following verses, was with them. Ver. 6. And there were four faces to one (המים or fimilitude), and four wings to one, בחל to them.' So there were at least two compound figures. Ver. 10. And the likeness of their faces; the face of a man, and the face of a lion, on the right fide, to them four; and the face of an ox to them four; and the face of an eagle to them four.' Ezekiel knew (ch. x. 1-20.) that these were cherubs. Ver 21. 'Four to one (cherub) and four wings to one.' This text also proves that the prophet saw more cherubs than one, and that each had four faces and four wings. And we may be certain that the cherubs placed in the holy of holies were of the form here described by the priest and prophet Ezekiel, because we have already feen from Exodus, 1 Kings, and 2 Chronicles, that they likewife had faces and wings, and because Ezekiel knew what he saw to be cherubs, and because there were no four-faced cherups any where else but in the holy of holies; for it is plain, from a comparison of Exod. xxvi. 1, 31. 1 Kings vi. 29, 32. and 2 Chron. iii. 14 with Ezekiel xli. 18, 19, 20. that the artificial cherubs on the curtains and vail of the tabernacle, and on the walls, doors, and vail of the temple, had only two faces; namely, those of a lion and of a man.

" For it must be observed further, that, as the word is used for one compound figure with four faces, and cricion in the plural for feveral fuch compounds (fee Exod. xxv. 18, 19. xxxvii. 8 1 Kings vi. 23-26), fo is ברוב applied to one of the cherubic animals, as to the ox, Ezek x 14.; (compare ch. i. 10) to the coupled cherub, or lion-man, Ezek xli. 18.: and ברובים to several of the cherubic animals, as to several oxen, I Kings vii. 36. (compare ver. 29.) to feveral coupled cherubs, Exod. xxvi 1. 1 Kings vi 32, 35. & al. I

proceed to shew

" Secondly, of what the cherubs were emblems, and

with what propriety.

"That the cherubic figures were emblems or reprefentatives of fomething beyond themselves is, I think, agreed by all, both Jews and Christians. question is, of what they were emblematical? To which I answer in a word, Those in the holy of holies were emblematical of the ever-bleffed Trinity in covenant to redeem man, by uniting the human nature to the Second Person; which union was fignified by the union of the faces of the lion and of the man in the cherubic exhibition, Ezek. i. 10. compare Ezek xli. 18, 19. The cherubs in the holy of holies were certainly intended to represent some beings in heaven, because St Paul has expreisly and infallibly determined that the holy of holies was a figure or type of heaven, even of that heaven where is the peculiar refidence of God (Heb. ix. 24). And therefore these cherubs represented either the ever bleffed Trinity with the man taken into the effence, or created fpiritual angels. The following reasons will, I hope, clearly prove them to be emblematical of the former, not of the latter:

" ist, Not of angels; because (not now to infift on other circumstances in the cherubic form) no tolcrable reason can be affigned why angels should be exhibited

with four faces apiece.

" 2dly, Because the cherubs in the holy of holies of tlic tabernacle were, by Jeliovah's order, ' made out of the matter of the mercy-feat, or beaten out of the same piece of gold as that was' (Exod. xxv. 18, 19, xxxvii, Cherus 9.). Now the mercy-feat, made of gold and crowned, was an emblem of the Divinity of Christ (See Rom. iii. 25.). The cherubs therefore represented not the angelic, but the Divine nature.

"3dly, The typical blood of Christ was sprinkled before them on the great day of atonement (compare Exod. xxxvii. 9. Lev. xvi. 14. Heb. ix. 7, 12.): And this cannot in any fense be referred to created angels, but must be referred to Jehovah only; because,

" 4thly, The high priest's entering into the holy of holies on that day, represented Christ's entering with his own blood into heaven 'to appear in the presence

of God for us' (Hcb. ix. 7, 24.). And,

" 5thly, When God ' raifed Chrift (the humanity) from the dead, he fet him at his own right hand in the heavenly places, far above, THEPANO, all principality and power, and might and dominion, and every name that is named, not only in this world, but also in that which is to come (Eph. i. 21.). Angels and authorities and powers being made subject unto him' (1 Peter 111. 22.)

" 6thly, The prophet Ezekiel faith (cli. x. 20.), "This is the living creature, and (which must mean one compound figure, comp. ver. 14.) that I faw' non instead of, a substitute of the Aleim of Israel. rnn, it is granted, may refer either to fituation or substitution, (see Gen. xxx. 2. l. 19.) as the sense requires. Here, notwithstanding what is faid ver. 19. the latter fense is preferable; because it was the glory of the God of Ifrael, i. e. the God-man in glory, (compare ch. i. 26.) not the Aleim (the Trinity) of Ifrael that were over the cherubim; and the text fays not, these were the living creatures, but, this was the living creature, which I faw תחת אלהי ישראל. Now the glory was over both the cherubims, ver. 19. but one compound cherub only was a substitute of the Aleim.

"If it should be here asked, Why then were there two compound cherubs in the holy of holies? I answer, Had there not in this place been two compound cherubs, it would have been naturally impossible for them to represent what was there designed; for otherwise, all the faces could not have looked inwards toward each other, and down upon the mercy feat, and on the interceding high prieft fprinkling the typical blood of Chrift, (fee Exod. xxxvii. 9.) and at the same time have looked outward toward the temple, לבית (Vulg. ad. domum exteriorem, to the outer house,) 2 Chron. iii. 13. Or, in other words, the Divine Persons could not have been represented as witnessing to each other's voluntary engagements for man's redemption, as beholding the facrifice of Christ's death, typissed in the Jewish church, and at the fame time as extending their gracious regards to the whole world. (See Ifa liv. 5. and Spearman's Enquiry, p. 382 edit Edinburgh.

"The coupled cherub, or lion-man, on the vail and curtains of the outer tabernacle, and on the vail, doors, and walls of the temple, accompanied with the emblematic palm tree, is fuch a striking emblem of the lion of the tribe of Judah (Rev. v. 5.) united to the man Christ Jesus, as is easy to be perceived, but hard to be evaded. These coupled cherubs appropriate the tabernacle or temple and their vails as emblems of Christ, and express in visible symbols what he and his apostles do in words. See John ii. 19, 21. Heb. viii, 2. ix. 11. rubim. x. 20. comp. Matt. xxvii. 51. And as the texts just cited from the New Testament afford us divine authority for afferting that the outer tabernacle or temple was a type of the body of Christ, fo they furnish us with an irrefragable argument to prove that the cherubs on their curtains, or walls could not reprefent angels. For did angels dwell in Christ's body? No surely: But ' in him dwelt all the fulness of the Godhead bo-

dily.' (Col. ii. 9.) "I go on to confider the propriety of the animals in the cherubic exhibition representing the Three Persons in the ever-bleffed Trinity. And here to obviate any undue prejudice which may have been conceived against the Divine Perfons being fymbolically represented under any animal forms whatever, let it be remarked that Jehovah appeared as three men to Abraham, (Gen. xviii.); that the serpent of brass set up by God's command in the wilderness was a type or emblem of Christ, Godman, lifted up on the cross (comp. Num. xxxi. 1-9. with John iii. 14, 15.); that at Jeius' baptism the Holy Spirit descended in a bodily shape, like a dove, upon him (Luke iii. 21, 22); that Christ, as above intimated, is expressly called the lion of the tribe of Judah (Rev. v. 5.); and continually in that fymbolical book tet before us under the similitude of a lamb. All these are plain foriptural representations, each of them admirably fuited, as the attentive reader will eafily observe, to the particular circumstances or specific defign of the exhibition. Why then should it appear a thing incredible, yea why not highly probable, that Jehovali Alein should, under the typical state, order his own Persons and the union of the manhood with the effence to be represented by animal forms in the cherubim of glory? Especially if it be confidered that the three animal forms, exclusive of the man (who stood for the very human nature itself) are the chief of their respective genera: the ox or bull, of the tame or graminivorous; the lion, of the wild or carnivorous; and the eagle, of the winged kind. - But this is by no means all: For. as the great agents in nature, which carry on all its operations, certainly are the fluid of the heavens, or, in other words, the fire at the orb of the fun, the light iffuing from it, and the spirit or gross air confantly supporting, and concurring to the actions and effects of the other two; to we are told (Pfal. xix. 1.) that מכבים כבוד אל the heavens (are) the means of declaring, recounting, or particularly exhibiting the glory of God, even his eternal power and godhead, as St Paul speaks, Rom. i. 20. And accordingly Jehovah himself is sometimes, though rarely (I prefirme for fear of miltakes) called by the very name שמיא or heavens in the Old Testament, see 2 Chron. xxxii. 20. (comp. 2 Kings xix. 14. Isa. xxxvii. 15.) Dan. iv. 23. or 26.; as he is more frequently expressed by Oupavos heaven in the New. (See Mat. xxi. 25. Mark xi. 30, 31. Luke xv. 18, 21. xx. 4, 5. John iii. 27.) Yea not only fo, but we find in the Scriptures both of the Old and New Testament, that the Persons of the eternal Three and their economical operations in the spiritual, are represented by the three conditions of the celestial fluid and their operations in the material world. Thus the peculiar emblem of the Word or Second Person is the wow or light, and he is and does that to the fouls or spirits of

men which the material or natural light is and does to

their bodies. (See inter al. 2 Sam. xxiii. 4. Ifa. xlix.

6. lx. 1. Mal. iv. 2. or iii. 20. Luke i. 78. ii. 32. John Cherubim. i. 4-9. viii. 12. xii. 35, 36, 46.) The Third Person has no other diffinctive name in fcripture but my in Hebrew, and Trever in Greek, (both which words in their primary sense denote the material spirit or air in motion), to which appellation the epithet wap, aying holy, or one of the names of God, is usually added: and the actions of the Holy Spirit in the spiritual system are described by those of the air in the natural. (See John iii. 8. xx. 22 Acts ii. 2.) Thus, then the Second and Third Persons of the ever-blessed Trinity are plainly represented in scripture by the material light and air. But it is further written, Jehovah thy Aleim is a consuming fire, Deut. iv. 24. (Comp. Deut. ix. 23. Heb. xii. 29. Psal. xxi. 10. lxxviii. 21. Nah. i. 2.) And by fire, derived either immediately or mediately from heaven, were the typical facrifices confumed under the old dispensation. Since, then, Jehovah is in fcripture reprefented by the material heavens, and even called by their name, and especially by that of fire, and fince the Second and Third Persons are exhibited refpectively by the two conditions of light and spirit, and fince fire is really a condition of the heavenly fluid as much distinct from the other two as they are from each other, it remains that the peculiar emblem of the First Person (as we usually speak) of the eternal Trinity, confidered with respect to the other two, be the fire.

"Bearing then in mind that the personality in Jehovah is in scripture represented by the material Trinity of nature; which also, like their divine antitype, are of one substance, that the primary scriptural type of the Father is fire; of the Word, light; and of the Holy Ghost, spirit, or air in motion; we shall easily perceive the propriety of the cherubic emblems. For the ox or bull, on account of his horns, the curling hair on his forehead, and his unrelenting fury when provoked (see Psal. xxii. 13.) is a very proper animal emblem of fire; as the lion from his usual tawny goldlike colour, his flowing mone, his shining eyes, his great vigilancy and prodigious thrength, is of light; and thus likewife the eagle is of the spirit or air in action, from his being chief among fowls, from his impetuous motion, (see 2 Sam. i. 23. Job ix. 26. Jer. iv. 13. Lam. iv. 19), and from his towering and surprising flights in the air (fee Job xxxix. 27. Prov xxiii. 5. xxx. 19. Ifa. xl. 31. and Bochart, vol. iii. page 173.) And the heathen used these emdematic animals, or the like, fometimes separate, sometimes joined, in various manners, as reprefentatives of the muterial Trinity of uature, which they adored. These particulars Mr Hutchinfon has proved with a variety of ufeful learning, vol. vii. p. 381. & feq. and any perfon who is tolerably acquainted with the heathen mythology will be able to increase his valuable collection with many instances of the same kind from modern as well as ancient accounts of the pagan religions.

"Thus, then, the faces of the ox, the lion, and the eagle, representing at second hand the Three Persons of Jehovah, the Father, the Word, and the Holy Spirit; and the union of the divine light with man being plainly pointed out by the union of the faces of the lion and the man (see Ezek. i. 10. xli. 18.), we may fafely affert, that the cherubim or glory (Heb. ix. 5.) in the holy of holies were divinely instituted and proper emblems of the Three Eternal Persons in covenant to

Cherubim. redeem man, and of the union of the divine and human any propriety, or without the greatest solecism, be said the iii. 24.) that immediately on Adam's expulsion from paradife, and the ceffation of the first or paradifiacal dispensation of religion, Jehovah Aleim himself set up these emblems, together with the burning slame Hutchinson's sense of that word; it being as contrary rolling upon itself, to keep the way to the tree of life; undoubtedly, confidering the fervices performed

through it " Thus far Mr Parkhurst; and to his differtation where is the man who will deny the merit of erudition, combined with ingenuity? 'To the latter part of his rea-

foning, however, objections obtrude themselves upon us of fuch force, that we know not how to answer them. The reader observes, that, according to this account, the cherubim are only at fecond hand emblematical of the Holy Trinity, and that the primary emblem is that fluid which the author conceives to fill the folar fystem, and to be one substance under the different appearances or modifications of fire, light, and grofs air. But unfortunately for this reasoning, we are as certain as we can be of any matter of fact, that fire and air are not one substance; that the gross air itself is compounded of very different substances; and that even light is a different substance from that which causes in us the sensation of heat, and to which modern chemists have given the name of caloric (See CHEMISTRY-Index in this Supplement). We admit, that the primary atoms of all matter may be fubstances of the very same kind, though we do not certainly know that they are: but this makes nothing for our author's hypothesis; because the sun and all the planets must, in that case, be added to his one substance, which would no longer appear under a triple form. Could it indeed be proved, that all men from Adam downwards, who made use of cherubic figures for the very same purpose with the ancient Jews, believed that fire, air, and light, are different modifications of the same substance, their belief, though erroneous, would be a sufficient foundation for our author's reason-

none that is fatisfactory could be brought. Our learned author, indeed, takes much for granted without proof. He has not proved, that anywhere the bull was the emblem or hieroglyphic of fire, the lion of light, or the eagle of air. We do not, it must be owned, know that such hieroglyphics were not used in Egypt and other countries before the introduction of alphabetical characters; but unless they were so used by Adam, all that is here faid of the propriety of these emblems must go for nothing: Indeed we see not their peculiar propriety. The tawny colour, flowing mane, and herceness of the lion, might, for any thing that we can perecive to the contrary, represent fire as fitly as the horns, curling hair, and fury of the bull; and if it be true, as is generally faid, that the eagle can look ileadily on the fun, he feems, of all the three, to be

ing; but of this no proof is attempted, and certainly

the fittest emblem of light.

But there are other objections to this interpretation of the word cherubim. The four animals in the Revelation, which were undoubtedly cherubim, as well as the four and twenty elders, fell down before the Lamb, *Ch. v. 8, and worshipped God *. Now, fays Dr Gregory Sharp, "it is scarce to be conceived, if these four beasts were re-

natures in the person of Christ. And we find (Gen. and described to fall down before and worship other emblematical representations of the same divine nature and perfections: And therefore, whatever these beatts were emblems of, they could not be cherubim in Mr to the rational explanation of a vision to say that one emblem of the divinity should worship another emblem before them, not to hinder, but to enable, man to pass of it, as it is contrary to the reason of mankind, and to all our notions either of the Godhead or of worship, to fay that the Trinity worshipped the Trinity, or any one Person in the Trinity."

This objection is admitted by our learned author to be a very plausible one. To us it appears unanswerable. He answers it, however, in the following words:

" Let it be carefully observed, that these representations in Rev. ch. v. and xix. are not only vifional but hieroglyphical, and therefore must be explained according to the analogy of fuch emblematical exhibitions; and as at ver. 6. 'the lamb, as it had been flain, having feven horns and feven eyes, standing in the midst of the throne, and of the four animals, and of the four andtwenty elders,' is evidently fymbolical of the Lamb of God now raised from the dead, and invested with all knowledge and power both in heaven and in earth; fo ' the four animals falling down before him' (ver. 8.), and, as it is expressed (ch. xix. 4.) ' worshipping God who fat upon the throne,' must, in all reason, be explained lymbolically likewife, not from any abstract or metaphyfical notions we may have framed to ourfelves of worship in general, but from the specific and peculiar circumstances of the case before us. likewise, when in 1 Chron. xxix. 20. 'All the congregation worshipped Jehovah and the king, namely David, the worthip to both is expressed by the same ftrong phrase - שחחוו ל prostrated themselves to, LXX. προσεκυνησαν; yet furely no one will fay that the people meant to worship David as God, but only to acknowledge him as king. So Adonijah, who had contested the crown with Solomon, came, משחתו and worshipped King Solomon, (1 Kings 1. 53.) not as God doubtlefs, but as king, thereby furrendering his own claim to the throne. However "contrary therefore it may be to the reason of mankind, and to all our notions either of the Godhead or of worship, to say that the Trinity worshipped the Trinity, or any one Person of the Trinity," i. e. with divine worship as a creature worships his Creator; yet it is by no means contrary to the rational and scriptural explanation of an emblematic vifion, to fay that the hieroglyphical emblems of the whole ever-bleffed Trinity fell down and worshipped the hieroglyphical emblem of the God-man, or God who fat upon the throne. Since fuch falling down, proftration, or worthipping, was the usual symbolical act, as it still is in the east, not only of divine worship, but of acknowledging the regal power to be in the perfon fo worshipped; and these acts of the cherubic animals in Rev. v. 6. xix. 4. meant nothing more than either a cession of the administration of all divine power to Christ God man, or a declaration of the divine Perfons, by their hieroglyphical representatives, that He must reign till all his enemies were made his footstool. Comp. Mat. xxviii. 18. 1 Cor. xv. 25."

With every inclination to honour the memory of Mr presentatives of the divine persons, that they could with Parkburst, who was certainly a scholar, and, which is

wix 4.

of more value, a pious and a good man, we cannot help borfe; then the boat; and before them all, four foot-fol. Chefs. confidering this answer as mere trifling. In the 18th Pfalm, the Lord is faid to "ride upon a cherub;" and in Ezekiel, chap is there is faid to have "been over the heads of the cherubim a throne, and upon that throne the likeness or appearance of a man," whom we take to be the Son of God incarnate. But is there any country in which the regal power of the fovereign is acknowledged by his riding, not upon his subjects, but upon other co-equal fovereigns? or, in which it is the custom for the fovereign to place his viceroy (for fuch our Saviour in his human nature certainly is) in his throne above himself?

We must therefore confess, that we know not of what the cherubic figures were emblematical, and that he who labours to establish the doctrine of the ever bleffed Trinity by fuch criticisms and reasonings as those which we have examined, is either a fecret enemy to

that doctrine, or a very injudicious friend.

CHESS, the celebrated game, of which a copious account has been given in the Encyclopædia, is affirmed by Sir William Jones to have been invented by the Hindoos. "If evidence were required to prove this fitic Re-fact (fays he *), we may be satisfied with the testimo. des, vol ny of the Perfians, who, though as much inclined as dem. 9. other nations to appropriate the ingenious inventions of a foreign people, unanimously agree that the game was imported from the west of India in the fixth century of our era. It feems to have been immemorially known in Hindostan by the name of Cheturanga, i. c. the four angá's, or members of an army; which are thefe, elephants, horses, chariots, and foot-soldiers; and in this fence the word is frequently used by epic poets in their descriptions of real armies. By a natural corruption of the pure Sanfcrit word, it was changed by the old Perfians into Chetrang; but the Arabs, who foon after took possession of their country, had neither the initial nor final letter of that word in their alphabet, and confequently altered it further into Shetranj, which found its way presently into the modern Persian, and at length into the dialects of India, where the true derivation of the name is known only to the learned. Thus has a very fignificant word in the facred language of the Brahmins been transformed by successive changes into axedrez, scacchi, échecs, chefs, and, by a whimsical concurrence of circumstances, has given birth to the English word check, and even a name to the exchequer of Great Britain."

It is confidently afferted, that Sanscrit books on chess exist in Bengal; but Sir William had seen none of them when he wrote the memoir which we have quoted. He exhibits, however, a description of a very ancient Indian game of the fame kind, but more complex, and in his opinion more modern, than the simple chess of the Perfians. This game is also called Chaturanga, but more frequently Chaturaji, or the four kings, fince it is played by four perfons representing as many princes, two allied armies combating on each fide. The description is taken from a book called Bhazvishya Purán; in which the form and principal rules of this factitious wasfare are thus laid down: "Eight squares being marked on all sides, the red army is to be placed to the east, the green to the fouth the yellow to the west, and the black to the north. Let the elephant (fays the author of the Purán) stand on the left of the king; next to him the

diers; but the boat must be placed in the angle of the board."

" From this passage (says the president) it clearly appears, that an army with its four angás must be placed on each fide of the board, fince an elephant could not stand, in any other position, on the left hand of each king; and RADHACANT (a Pandit) informed me, that the board confisted, like our's, of 64 squares, half of them occupied by the forces, and half vacant. He added, that this game is mentioned in the oldest law books. and that it was invented by the wife of a king, to amufe him with an image of war, while his metropolis was befieged in the second age of the world. A slip or boat is abfurdly fubflituted, we fee, in this complex game for the rat'h, or armed chariot, which the Bengalese pronounce rot'h, and which the Persans changed into rokh; whence came the rook of fome European nations; as the vierge and fal of the French are supposed to be corruptions of ferz and fil, the prime minister and elephant of the Perfians and Arabs."

As fortune is supposed to have a great share in deciding the fate of a battle, the use of dice is introduced into this game to regulate its moves; for (fays the Puran) " if cinque be thrown, the king or a paron must be moved; if quatre, the elephant; if trois, the horse; and if deux, the loat. The king passes freely on all sides, but over one square only; and with the same limitation. the pawn moves, but he advances straight forward, and kills his enemy through an angle. The elephant marches in all directions as far as his driver pleases; the horse

runs obliquely, traverfing the squares; and the ship goes over two squares diagonally." The elephant, we find, has the powers of our queen, as we are pleased to call the general or minister of the Persians; and the ship

has the motion of the piece to which we give the unaccountable appellation of bishop, but with a restriction

which must greatly lessen its value.

In the Puran are next exhibited a few general rules. and superficial directions for the conduct of the game. Thus, "the pawns and the ship both kill and may be voluntarily killed; while the king, the clephant, and the horse, may flay the foe, but must not expose themselves. to be slain. Let each player preserve his own forces. with extreme care, fecuring his king above all, and not facrificing a superior to keep an inferior piece." Here (fays the prefident) the commentator on the Purán obferves, that the borfe, who has the choice of eight moves from any central position, must be preferred to the stip, which has only the choice of four. But the argument. would not hold in the common game, where the bishop and tower command a whole line, and where a knight is always of less value than a tower in action, or the bishop of that Ede on which the attack is begun. "It is by the overbearing power of the elephant (continues the Purán) that the king fights boldly; let the whole army, therefore, be abandoned in order to feeme the elephant. The king must never place one elephant before another, unless he be compelled by want of room, for he would thus commit a dangerous fault; and if he can flay one of two hostile elephants, he must destroy that on his left hand."

All that remains of the paffage which was copied for Sir William Jones relates to the feveral modes in which a partial fuccess or complete victory may be obtained

Chevrette.

by any one of the four players; for, as in a dispute between two allies, one of the kings may fometimes affume the command of all the forces, and aim at a feparate conquest. First, "When any one king has placed himself on the square of another king (which advantage is called finh afana or the throne) he wins a stake, which is doubled if he kill the adverse monarch when he seizes his place; and if he can feat himself on the throne of his ally, he takes the command of the whole army." Secondly, "If he can occupy fucceffively the thrones of all the three princes, he obtains the victory, which is named cheturoji; and the stake is doubled if he kill the last of the three, just before he takes possession of his throne; but if he kill him on his throne, the stake is quadrupled. Both in giving the finhafana and the cheturaji the king must be supported by the elephants, or by all the forces united." Thirdly, "When one player has his own king on the board, but the king of his partner has been taken, he may replace his captive ally, if he can feize both the adverse kings; or if he cannot effect their capture, he may exchange his king for one of them, against the general rule, and thus redeem the allied prince, who will fupply his place." This advantage has the name of uripacrishta or recovered by the king. Fourthly, " If a pawn can march to any Iquare on the opposite extremity of the board, except that of the king, or that of the ship, he assumes whatever power belonged to that square." Here we find the rule, with a flight exception, concerning the advance. ment of parwns, which often occasions a most interesting struggle at our common chess; but it appears that, in the opinion of one ancient writer on the Indian game, this privilege is not allowable when a player has three pawns on the board; but when only one pawn and one ship remains, the pawn may advance even to the square of a king or a ship, and assume the power of either. Fifthly, According to the people of Lance, where the game was invented, "there could be neither victory nor defeat if a king were left on the plain with out force; a fituation which they named cacacasht' ba." Sixthly, "If three ships happen to meet, and the fourth ship can be brought up to them in the remaining angle, this has the name of vribannauca; and the player of the fourth feizes all the others."

The account of this game in the original Sanscrit is in verse, and there are two or three couplets still remaining, so very dark, either from an error in the manufeript, or from the antiquity of the language, that Sir William Jones could not understand the Pandit's explanation of them, and suspects, that even to him they gave very indistinct ideas. It would be easy, however, he thinks, if it be judged worth while, to play at the game by the preceding rules; and a little practice would

perhaps make the whole intelligible.

CHEVRETTE, in artillery, is an engine employed to raise guns or mortars into their carriage. It is formed of two pieces of wood about four feet long, standing upon a third, which is fquare. The uprights are about a foot afunder, and pierced with holes exactly opposite to one another, to receive a bolt of iron, which is put in, either higher or lower at pleasure, to ferve as a support to a handspike, by which the gun is raised up.

By the author of the Military Guide, this is faid to be Change the most useful of all the inventions for raising guns into their carriages; and it feems these inventions have been many.

CHICHA, the name given by the natives to the island of Jesso, which lies to the fouth of Oku-Jesso, or Segalian Island. See SEGALIAN in this Supplement.

CHIMERE, the upper robe worn by bishops in church and in the House of Peers, to which the lawn fleeves are generally fewed. Before the Reformation, and even after it till the reign of Queen Elizabeth, the chimere was always of fearlet filk; but bishop Hooper, scrupling first at the robe itself, and then at the colour of it, as too light and gay for the epifcopal gravity, the chimere was afterwards made of black fatin. The ar-

chiepiscopal chimere has a long train.

CHIMNEY, a particular part of a house well known, which Professor Beckmann has, in our opinion, proved to be an invention comparatively modern. It would be very unfair dealing in us to give even a large abstract of one of the most curious differtations of a eurious book, which has been but lately published, and thereby injure the interest of him to whom the native of Britain is indebted for the pleasure of perusing it in his own No man, however, can blame us for here stating, in support of our own opinion, the professor's anfwer to the passage of Ferrari, which we have quoted under the word CHIMNEY in the Encyclopædia.

"When the triumveri, fays Appian *, caused those * Debit who had been profcribed by them to be fought for by wird. His the military, fome of them, to avoid the bloody handsp 962 ea of their perfecutors, hid themselves in wells, and others, Tolink as Ferrarius translates the words, in fumaria sub tedo, qua scilicet sumus e tecto evolvitur (A). The true translation, however. (fays Mr Beckmann) is fumofa canacula. The principal persons of Rome endeavoured to conceal themselves in the smoky apartments of the upper story under the roof, which, in general, were inhabited only by poor people; and this feems to be confirmed by what Juvenal + expressly fays, Rarus venit in canacula + Sat x

"Those passages of the ancients which speak of fmoke rifing up from houses, have with equal impropriety been supposed to allude to chimneys, as if the fmoke could not make its way through doors and win-Seneca t writes, Last evening I had some Epist a friends with me, and on that account a ftronger smoke was raifed; not fuch a fmoke, however, as burftsforth from the kitchens of the great, and which alarms the watchmen, but such a one as fignifies that guests are arrived.' Those whose judgments are not already warped by prejudice, will undoubtedly find the true fense of these words to be, that the fmoke forced its way through the kitchen windows. Had the houses been built with chimney funnels, one cannot conceive why the watchmen fhould have been alarmed when they observed a ftronger smoke than usual arising from them; but as the kitchens had no conveniences of that nature, an apprehension of fire, when extraordinary entertainments were to be provided in the houses of the rich for large companies, feems to have been well founded; and on fuch occasions people appointed for that purpose were **ftationed**

flationed in the neighbourhood to be conflantly on the watch, and to be ready to extinguin the flames in cale a fire should happen. There are many other passages to be found in Roman authors of the like kind, which it is hardly necessary to mention; fuch as that of Virgil+,

Et jam fumma procul villarum culmina fumant." and the following words of Plautus *, descriptive of a

· Quin divum atque hominum clamat continuo fidem,

Suam rem periisse, seque eradicarier,

De fuo tigillo fumus fi qua exit foras.'

In the Vespæ of Aristophanes, referred to in the Encyclopædia, old Philocleon wifhes to escape through the kitchen. Some one asks, "What is that which makes a noise in the chimney?" "I am the smoke (replies the old man), and am endeavouring to get out at the chimney." "This passage, however (fays the professor) which, according to the usual translation, feems to allude to a common chimney, can, in my opinion, especially when we consider the illustration of the scholiasts, be explained also by a simple hole in the roof, as Reiske has determined; and indeed this appears to be more probable, as we find mention made of a top or covering t with which the hole was closed."

In the Encyclopædia we have faid, that the instances of climneys remaining among the ruins of ancient buildings are few, and that the rules given by Vitruvius for building them are obscure; but we are now satisfied that there are no remains of ancient chimneys, and that Vitruvius gives no rules, either obscurc or perspicuous. for building what, in the modern acceptation of

the word, deserves the name of a chimney.

" The ancient mason-work still to be found in Itay does not determine the question. Of the walls of towns, temples, ampihtheatres, baths, aqueducts, and bridges, there are some though very imperfect remains, in which chimneys cannot be expected; but of common dwelling houses none are to be feen, except at Herculaneum, and there no traces of chimneys have been discovered. The paintings and pieces of sculpture which are preferved, afford us as little information; for nothing can be perceived in them that bears the smallest resemblance to a modern chimney.

" If there were no funnels in the houses of the ancients to carry off the smoke, the directions given by Columella, to make kitchens to high that the roof should not catch fire, was of the utmost importance. An accident of the kind, which that author feems to have apprehended, had almost happened at Beneventum, when the landlord who entertained Mæcenas and his company was making a strong fire in order to get some birds

sooner roasted.

ubi sedulus hospes

' Pæne arfit, macros dum turdos veisat in igne;

' Nam vaga per veterem dilapfo flamma culinam

'Vulcano femmum properabat lambere tectum +.'

t. 5. Had there been chimneys in the Roman houses, Vitruvius certainly would not have failed to describe their construction, which is sometimes attended with considerable difficulties, and which is intimately connected with the regulation of the plan of the whole edifice. He does not, however, fay a word on this subject; peither

SUPPL. VOL. I. Part II.

does Julius Pollux, who has collected with great care Chimney. the Greek names of every part of a dwelling house; and Grapaldus, who in later times made a collection of the Latin terms, has not given a Latin word experfive of a modern chimney *."

e of a modern chimney *."

Our author admits the derivation of the word chim-paidi de para ney to be as we have given it in the Encyclopædia; but ithes adium (fays he) " Caminus fignified, as far as I have been able iibii. to learn, first a chemical or metallurgic furnace, in which a crucible was placed for melting and refining metals; fecondly, a fmith's forge; and, thirdly, a hearth on which portable stoves or fire-pans were placed for warming the apartment. In all these, however, there appears no trace of a chimney." Herodotus relates (lib. viii c. 137.), that a king of Libya, when one of his fervants asked for his wages, offered him in jest the sun, which at that time shone into the house through an opening in the roof, under which the fire was perhaps made in the middle of the edifice. If fuch a hole must be called a chimney, our author admits that chimneys were in use among the ancients, especially in their kitchens; but it is obvious that fuch chimneys bore no refemblance to our's, through which the fun could not dart his rays upon the floor of any apartment.

" However imperfect may be the information which can be collected from the Greek and Roman authors refpecting the manner in which the ancients warmed their apartments, it nevertheless shews that they commonly used for that purpose a large fire pau or portable stove, in which they kindled wood, and, when the wood was well lighted, carried it into the room, or which they filled with burning coals When Alexander the Great was entertained by a friend in winter, as the weather was cold and raw, a fmall fire baf in was brought into the apartment to warm it. The prince, observing the fize of the vessel, and that it contained only a few coals, defired his hoft, in a jeering manner, to bring more wood or frankincenfe; giving him thus to underland that the fire was fitter for burning perfumes than to produce heat. Anacharsis, the Scythian philosopher, though displeased with many of the Grecian customs, praifed the Greeks, however, because they shut out the fmoke and brought only fire into their houses *. We * Plutarch. are informed by Lampridius, that the extravagant He-Sympos. liogabulus caused to be burned in these stoves, instead lib. vi. 7. of wood, Indian fpiceries and colly perfumes +. It is + #1 Lamalso worthy of of notice, that coals were found in some prid. Vita of the apartments of Herculancum, as we are told by Heliogab. Winklemann, but neither stoves nor chimneys."

It is well known to every scholar, that the useful arts of life were invented in the east, and that the customs, manners, and furniture of eastern nations, have remained from time immemorial almost unchanged. In Perfia, which the late Sir William Jones feems to have confidered as the original country of mankind, the mc. thods employed by the inhabitants for warming themfelves have a great resemblance to those employed by the ancient Greeks and Romans for the fame purpose. According to De la Valle, the Persians make fires in their apartments, not in chimneys as we do, but in floves in the earth, which they call tennor. "These stoves confitt of a fcuare or round hole, two fpans or a little more in depth, and in shape not unlike an Italian cask. That this hole may throw out heat foouer, and with more thrength, there is placed in it an iron restal of the

Chimney. fame fize, which is either filled with burning coals, or a fire of wood and other inflammable substances is made in it. When this is done, they place over the hole or flove a wooden top, like a small low table, and spread above it a large coverlet quilted with cotton, which hangs down on all fides to the floor. This covering condenses the heat, and causes it to warm the whole apartment. The people who eat or converse there, and some who sleep in it, lie down on the floor above the carpet, and lean, with their foulders against the wall, on square cushions, upon which they sometimes also fit; for the tennor is constructed in a place equally distant from the walls on both fides. Those who are not very cold only put their feet under the table or covering; but those who require more heat can put their hands under it, or creep under it altogether. By thefe means the stove diffuses over the whole body, without caufing uneafinefs to the head, fo penetrating and agreeable a warmth, that I never in winter experienced any thing more pleasant. Those, however, who require less heat let the coverlet hang down on their side to the floor, and enjoy without any inconvenience from the stove the moderately heated air of the apartment. They have a method also of stirring up or blowing the fire when necessary, by means of a small pipe united with the tennor or stove under the earth, and made to project above the floor as high as one chooses; fo that the wind, when a person blows into it, because it has no other vent, acts immediately upon the fire like a pair of bellows. When there is no longer occasion to use this stove, both holes are closed up, that is to fay, the mouth of the stove and that of the pipe which conveys the air to it, by a flat stone made for that purpose. Scarcely any appearance of them is then to be perceived, nor do they occasion inconvenience, especially in a country where it is always customary to cover the sloor with a carpet, and where the walls are plastered. In many parts these ovens are used to cook victuals, by placing kettles over them. They are employed also to bake bread; and for this purpose they are covered with a large broad metal plate, on which the cake is laid; but if the bread is thick and requires more heat, it is put into the stove itself."

Our learned author having proved, to our entire fatisfaction, that chimneys, such as we have now in every comfortable room, were unknown to the most polished nations of antiquity, fets himfelf to inquire into the era of their invention; and the oldest account of them which he finds is an infeription at Venice, which relates, that in the year 1347 a great many chimneys were thrown down by an earthquake. It would appear, however, that in some places they had been in use for a considerable time before that period; for De Gataris, in his history of Padua, relates, that Francesco de Carraro, lord of Padua, came to Rome in 1368, and finding no chimneys in the inn where he lodged, because at that time fire was kindled in a hall in the middle of the floor, he caused two chimneys like those which had long been used at Padua to be constructed by masons and carpenters, whom he had brought along with him. Over these chimneys, the first ever seen at Rome, he affixed his arms, which were still remaining in the time of De Gataris, who died of the plague in 1405.

Though chimneys have been thus long in use, they are yet far enough from being brought to perfection.

There is hardly a modern house, especially if highly fi- Chies nished, in which there is not one room at least liable to be filled with finoke when it is attempted to be heated by an open fire; and there are many houses so infested with this plague, as to be almost uninhabitable during the winter months; not to mention other great defects in common chimneys, which not being fo obvious have attracted less attention. Many ingenious methods have been proposed to cure smokey chimneys in every stuation (fee Smoke, Encycl.); but Count Rumford's Effay on this fubject contains the most valuable directions that we have feen, not only for removing the inconveniency of fmoke, but likewise for increasing the heat of the room by a diminished consumption of fuel.

To those who are at all acquainted with the nature and properties of elattic fluids, it must be obvious, that the whole mystery of curing smokey chimueys consists in finding out and removing the accidental causes which prevent the heated fmoke from being forced up the chimney by the preflure of the cool and therefore heavier air of the room. Though these causes are various, yet, fays our author, that which will most commonly be found to operate, is the bad confirmation of the chimney in the neighbourhood of the fire-place. "The great fault of all the open fire places or chimneys for burning wood or coals in an open fire now in common use is, that they are much too large; or rather it is the throat of the chimney, or the lower part of its open canal, in the neighbourhood of the mantle, and immediately over

the fire, which is too large." To this fault, therefore, the attention should be first turned in every attempt which is made to improve the construction of chimneys; for however perfect a fire-

place may be in other respects, if the opening left for the passage of the smoke is larger than is necessary for that purpose, nothing can prevent the warm air of the room from escaping through it; and whenever this happens, there is not only an unnecessary loss of heat, but the warm air which leaves the room to go up the chimney being replaced by cold air from without, draughts of cold air cannot fail to be produced in the room, to the great annoyance of those who inhabit it. But although both these evils may be effectually remedied by reducing the throat of the chimney to a proper fize, yet in doing this feveral precautions will be necesfary. And first of all, the throat of the chimney sliould be in its proper place; that is to fay, in that place in which it ought to be, in order that the afcent of the fmoke may be most facilitated: now as the smoke and hot vapour which rife from a fire naturally tend upwards, the proper place for the throat of the chimney is evidently perpendicularly over the fire.

But there is another circumstance to be attended to in determining the proper place for the throat of a chimney, and that is, to ascertain its distance from the fire, or how far above the burning fuel it ought to be placed. In determining this point there are many things to be considered, and several advantages and disadvantages to be weighed and balanced.

As the smoke and vapour which ascend from burning fuel rife in consequence of their being rarefied by heat, and made lighter than the air of the furrounding atmosphere; and as the degree of their rarefaction, and consequently their tendency to rise, is in proportion to the intensity of their heat; and further, as they are hotter near the fire than at a greater distance from it-it is clear that the nearer the throat of a chimney is to the fire, the stronger will be what is commonly called its draught, and the less danger there will be of its smoking. But, on the other hand, when the draught of a chimney is very strong, and particularly when this strong draught is occasioned by the throat of the chimney being very near the fire, it may so happen that the draught of air into the fire may become fo strong as to cause the fuel to be confumed too rapidly. There are likewife feveral other inconveniences which would attend the placing of the throat of a chimney very near the burn-

The position of the throat of a chimney being once determined, the next points to be ascertained are its fize and form, and the manner in which it ought to be connected with the fire-place below, and with the open canal of the chimney above. But as these investigations are intimately connected with those which relate to the form proper to be given to the fire-place itself, we mult

confider them all together.

Now the defign of a chimney fire being fimply to warm a room, it is necessary, first of all, to contrive matters so that the room shall be actually warmed; secondly, that it be warmed with the smallest expence of fuel possible; and, thirdly, that in warming it, the air of the room be preferved perfectly pure, and fit for refpiration, and free from smoke and all disagreeable fmells.

To determine in what manner a room is heated by an open chimney fire, it will be necessary first of all to to find out under what form the heat generated in the combustion of the fuel exists, and then to see how it is communicated to those bodies which are heated by it.

In regard to the first of these subjects of inquiry, it is quite certain that the heat which is generated in the combustion of the fuel exists under two perfectly distinct and very different forms. One part of it is combined with the fmoke, vapour, and heated air which rife from the burning ruel, and goes off with them into the upper regions of the atmosphere; while the other part, which appears to be uncombined, or, as fome ingenious philosophers have supposed, combined only with light, and therefore called radiant heat, is fent off from the fire in

rays in all possible directions.

With respect to the second subject of inquiry, namely, how this heat, existing under these two different forms, is communicated to other bodies, it is highly probable that the combined heat can only be communicated to other bodies by actual contact with the body with which it is combined; and with regard to the rays which are fent off by burning fuel, it is certain that they communicate or generate heat only when and where they are stopped or absorbed. In passing through air, which is transparent, they certainly do not communicate any heat to it; and it feems highly probable that they do not communicate heat to folid bodies by which they are reflected.

As it is the radiant heat alone which can be employed in warming a room, when fuel is burnt for this purpose in an open fire place, it becomes an object of much importance to determine how the greatest quantity of it may be generated in the combustion of the fuel, and how the greatest proportion possible of that generated may be brought into the room.

Now the quantity of radiant heat generated in the Chimneys combustion of a given quantity of any kind of fuel depends very much upon the management of the fire, or upon the manner in which the fuel is confumed. When the fire burns bright, much radiant heat will be fent off from it; but when it is smothered up, very little will be generated, and indeed very little combined heat that can be employed to any ufeful purpose: most of the heat produced will be immediately expended in giving elasticity to a thick dense vapour or smoke, which will be feen rifing from the fire; and the combustion being very incomplete, a great part of the inflammable matter of the fuel being merely rarefied and driven up the chimney without being inflamed, the fuel will be wasted to little purpose. And hence it appears of how much importance it is, whether it be confidered with a view to economy, or to cleanlines, comfort, and elegance, to pay due attention to the management of a

chimney fire.

Nothing can be more perfectly void of common fense, and wasteful and slovenly at the same time, than the manner in which chimney fires, and particularly where coals are burned, are commonly managed by fervants. They throw on a load of coals at once, through which the flame is hours in making its way; and frequently it is not without much trouble that the fire is prevented from going quite out. During this time no heat is communicated to the room; and what is still worse, the throat of the chimney being occupied merely by a heavy dense vapour, not possessed of any considerable degree of heat, and confequently not having much elasticity, the warm air of the room finds less difficulty in forcing its way up the chimney and escaping than when the fire burns bright. And it happens not unfrequently, especially in chimneys and fire places illconstructed, that this current of warm air from the room which presses into the chimney, crossing upon the current of heavy fmoke which rifes flowly from the fire, obstructs it in its ascent, and beats it back into the room; hence it is that chimneys fo often smoke when too large a quantity of fresh coals is put upon the fire. So many coals should never be put on the fire at once as to prevent the free passage of the slame between them. In short, a fire should never be smothered; and when proper attention is paid to the quantity of coals put on, there will be very little use for the poker; and this circumstance will contribute very much to cleanliness, and to the preservation of furniture.

As we have feen what is necessary to the generation of the greatest quantity of radiant heat, it remains to be determined how the greatest proportion of that which is generated and fent off from the fire in all directions may be made to enter the room, and affift in warming it.

This must be done, first, by causing as many as posfible of the rays, as they are fent off from the fire in ftraight lines, to come directly into the room; which can only be effected by bringing the fire as far forward as possible, and leaving the opening of the fire-place as wide and as high as can be done without inconvenience: and, fecondly, by making the fides and back of the fire-place of fuch a form, and constructing them of fuch materials, as to cause the direct rays from the fire, which strike against them, to be sent into the room by reflection in the greatest abundance.

Now it will be found upon examination, that the best 3 F 2 form

Chimney. form for the vertical fides of a fire-place, or the covings (as they are called), is that of an upright plane, making an angle with the plane of the back of the fireplace of about 135 degrees .-- According to the prefent construction of chimneys, this angle is sometimes only 92, and very feldom above 100 or 110 degrees; but it is obvious, that in all these cases the two fides or covings of the fire place are very ill-contrived for throwing into the room by reflection the rays from the fire which fall upon them.

With regard to the materials which should be employed in the construction of fire places, particularly the backs and covings, it is obvious that those are to be preferred which alforb the leaft, and of course reflett the greatest quantity of radiant heat. Iron, therefore, and, in general, metals of all kinds, are the very worst materials which can possibly be employed for the backs and covings of chimneys; whilst fire stone whitewalled, or common bricks and mortar, covered with a thin coating of plaster, and white-washed, answer the purpose extremely well. A white colour should, indeed, be always given to the infide of a chimney of whatever materials it be confirmed; and black, which is at prefent fo common, should be carefully avoided, because white reflects the most, and black the least, radiant heat. The grate, however, cannot well be made of any thing else than iron; but there is no necessity whatever for that immense quantity of iron which furrounds grates as they are commonly fitted up, and which not only renders them very expensive, but effentially injures the fire-place.

To have only pointed out the faults of the chimneys in use, without shewing how these fauls may be corrected, would have been a work of very little value; but the Count's Treatife is complete, and contains the plainest directions for the construction of fire-places. These directions are introduced by an explanation of some technical words and expressions. Thus, by the throat of a chimney, already mentioned, he means the lower extremity of its canal, where it unites with the upper part of its open five place. This throat is commonly found about a foot above the level of the lower part of the mantle, and it is sometimes contracted to a smaller fize than the rest of the canal of the chimney, and some-

times not.

Plate XX.

Fig 1. shews the fection of a chimney on the common construction, in which de is the throat.

Fig. 2. shews the fection of the fame chimney altered and improved, in which di is the reduced throat.

The breast of a chimney is that part of it which is immediately behind the mantle. It is the wall which forms the entrance from below into the throat of the chimney in front, or towards the room. It is opposite to the upper extremity of the back of the open fire place, and parallel to it: in short, it may be faid to be the back part of the mantle itself .- In the figures 1. and 2. it is marked by the letter d. The width of the throat of the chimney (de fig. 1. and di fig. 2.) is taken from the breast of the chimney to the back, and its length is taken at right angles to its width, or in a line parallel to the mantle (a fig. 1. and 2.).

The bringing forward of the fire into the room, or

rather bringing it nearer to the front of the opening of the fire place, and the diminishing of the throat of the chimney, being two objects principally had in view in

the alterations in fire-places proposed by the Count, it Chais evident that both thefe may be attained merely by bringing forward the back of the chimney. question therefore is, How far it should be brought forward? The answer is short, and easy to be underflood; bring it forward as far as possible, without diminishing too much the passage which Bust be left for the fmoke. Now as this passage, which in its narrowet part he calls the throat of the chimney, ought, for reafons which have been already explained, to be immediately, or perpendicularly over the fire, it is evident that the back of the chimney must always be built perfecily upright. To determine, therefore, the place for the new back, or how far precifely it ought to be brought forward, nothing more is necessary than to alcertain how wide the throat of the chimney ought to be left, or what space must be left between the top of the breaft of the chimney where the upright canal of the chimney begins, and the new back of the fire place carried up perpendicularly to that height.

Numerous experiments have convinced the Count, that, all circumstances being well considered, and the advantages and difadvantages compared and balanced, four inches is the best width that can be given to the throat of a chimney, whether the fire place be defined to burn wood, coals, turf, or any other fuel. In very large halls where great fires are kept up, it may fometimes, though very rarely, be proper to increase this width to four inches and a half, or even to five inches.

The next thing to be confidered is the width which it will be proper to give to the back of the chimney; and, in most cases, this should be one-third of the width of the opening of the fire-place in front. It is not indeed abfolutely necessary to conform with rigour to this decision, nor is it always possible; but it should invariably be conformed to as far as circumstances will per-Where a chimney, fays the Count, is defigned for warming a room of a middling fize, and where the thickness of the wall of the chimney in front, measured from the front of the mantle to the breast of the chimney, is nine inches, I should fet off four inches more for the width of the throat of the chimney, which, suppofing the back of the chimney to be built upright, as it always ought to be, will give thirteen inches for the depth of the fire-place, measured upon the hearth, from the opening of the fire-place in front to the back. In this cafe, thirteen inches would be a good fize for the width of the back; and three times thirteen inches, or 39 inches, for the width of the opening of the fireplace in front; and the angle made by the back of the fire-place and the fides of it, or covings, would be just 135 degrees, which is the best position they can have for throwing heat into the room. This position, indeed, it may fometimes be impossible to attain in altering chimneys already built; but a deviation from it of two or three degrees will be of no great confequence; for the points of by much the greatest importance in altering fire-places upon the principles here recommended, are the bringing forward the back to its proper place, and making it of the proper width.

Provision, however, must be made for the passage of the chimney-sweeper up the chimney; and this may eafily be done in the following manner: In building up the new back of the fire-place; when this wall (which need never be more than the width of a fingle

brick in thickness) is brought up so high that there remains no more than about ten or eleven inches between what is then the top of it and the infide of the mantle, or lower extremity of the breast of the chimney, an opening or door-way, eleven or twelve inches wide, must be begun in the middle of the back, and continued quite to the top of it, which, according to the height to which it will commonly be necessary to carry up the back, will make the opening abundantly fufficient to let the chimney-fweeper pafs. When the fire-place is finished, this door-way is to be closed by a tile or fit piece of stone placed in it without mortar, and by means of a rabbit made in the brick-work, confined in its place in fuch a manner as that it may be eafily removed when the chimney is to be fwept, and reflored to its place when that work is over. Of this contrivance the reader will be able to form a clear conception from fig. 2. which represents the fection of a chimney after it has been properly altered from what is exhibited in fig. 1. In this improved chinancy k l is the new back of the fire place; li the tile or stone which closes the door-way for the chimney-sweeper; di the throat of the chimney narrowed to four inches; is the mantle, and h the stone placed under the mantle, supposed to have been too high, in order to diminish the height of the opening of the fire-place in front.

It has been observe! above, that the new back, which it will always be found necessary to build in order to being the fire fufficiently forward, in altering a chimney confiructed on the common principles, need never be thicker than the width of a common brick. fame may be faid of the thickness necessary to be given to the new fides or covings of the chimney; or if the new back and covings are confiructed of stone, one inch and three quarters, or two inches in thickness, will be sufficient. Care should be taken in building up these new walls to unite the back to the covings in a folid

Whether the new back and covings are confiructed of flone or built of bricks, the space between them and the old back and covings of the chimney ought to be tilled up, to give greater folidity to the structure. This may be done with loofe rubbish, or pieces of broken bricks or stones, provided the work be strengthened by a few layers or courses of bricks laid in mortar; but it will be indispensably necessary to finish the work where these new walls end, that is to say, at the top of the throat of the chimney, where it ends abruptly in the open canal of the chimney, by a horizontal course of bricks well fecured with mortar. This course of bricks will be upon a level with the top of the door-way left for the chimney sweeper; and the void behind the doorway must be covered with a horizontal stone or tile, to be removed at the fame time the door is removed, and for the same purpose.

From these descriptions it is clear, that where the throat of the chimney has an end, that is to fay, where it enters into the lower part of the open canal of the chimney, there the three wails which form the two covings and the back of the fire-place all end abruptly. It is of much importance that they should end in this manuen: for were they to be sloped outward, and raifed in fuch a manner as to fwell out the upper extremity of the throat of the chimney in the form of a trumpet, and increase it by degrees to the fize of the canal

413 of the chimney, this manner of uniting the lower extre. Chimney. mity of the canal of the chimney with the throat would tend to affift the winds, which may attempt to blow down the chimney, in forcing their way through the throat, and throwing the fmoke backward into the room; but when the throat of the chimney ends abruptly, and the ends of the new walls form a flat horizontal furface, it will be much more difficult for any wind from above to find and force its way through the narrow passage of the throat of the chimney.

As the two walls which form the new covings of the chimney are not parallel to each other, but inclined, prefenting an oblique furface towards the front of the chimney, and as they are built perfectly upright, and quite flat, from the hearth to the top of the throat, where they end, it is evident that an horizontal fection of the throat will not be an oblong square; but its deviation from that form is a matter of no consequence; and no attempts should ever be made, by twisting the covings above where they approach the breast of the chimney, to bring it to that form All twiffs, bends, prominences, excavations, and other irregularities of form in the covings of a chimney, never fail to produce eddies in the current of air which is continually paffing into, and through, an open fire place in which a fire is burning; and all fuch eddies diffurb either the fire or the afcending current of fmoke, or both; and not unfrequently cause the imoke to be thrown back into the room. Hence it appears, that the covings of chimneys should never be made circular, or in the form of any other curve, but always quite flat.

For the same reason, that is to say, to prevent eddies, the breaft of the chimney, which forms that fide of the throat that is in front or nearest to the room, should be neatly cleaned off, and its surface made quite regular and fmooth. This may be eafily done by covering it with a coat of plaster, which may be made thicker or thinner in different parts, as may be necessary in order to bring the breakt of the chimney to be of

the proper form. With regard to the form of the breast of a chimney, this is a matter of very great importance, and which ought always to be particularly attended to. The worth torm it can have is that of a vertical plane or upright. flat; and next to this the worlt form is an inclined plane. Both these forms cause the current of warm air from the room, which will, in spite of every precaution, fometimes find its way into the chimney, to crofs upon the current of smoke which rifes from the fire in a manner most likely to embarrass it in its ascent, and drive.

The current of air which, paffing under the mantle, gets into the chimney, should be made gradually to tend its course upwards; by which means it will unite quietry with the ascending current of smoke, and will be less likely to check it, or force it back into the room. No v this may be effected with the greatest ease and certainty, merely by rounding off the breaft of the chimney or back part of the mantle, instead of leaving it flat or full of holes and corners; and this of course ought always to be done.

Having thus afcertained the form and polition of the new covings, the ingenious author next turns his attention to the height to which they should be carried. This will depend not only on the height of the mantle,

Chimney, but also, and more especially, on the height of the breast of the chimney, or of that part of the chimney where the breast ends and the upright canal begins .-The back and covings must rife a few inches, five or fix for instance, higher than this part, otherwise the throat of the chimney will not be properly formed; but no advantage would be gained by carrying them

> One important circumstance respecting chimney fireplaces still remains to be confidered; and that is the grate. In placing the grate, the thing principally to be attended to is, to make the back of it coincide with the back of the fire-place. But as many of the grates now in common use will be found to be too large, when the fire places are altered and improved, it will be nedeffary to diminish their capacities by filling them up at the back and fides with pieces of fire-stone. When this is done, it is the front of the flat piece of fire-stone which is made to form a new back to the grate, which must be made to coincide with, and make part of the back of the fire-place. - But in diminishing the capacities of grates with pieces of fire-stone, care must be taken not to make them too narrow.

The proper width for grates destined for rooms of a middling fize will be from fix to eight inches, and their length may be diminished more or less according as the room is heated with more or less difficulty, or as the weather is more or less severe. - But where the width of a grate is not more than five inches it will be very

difficult to prevent the fire from going out.

It frequently happens that the iron backs of grates are not vertical, or upright, but inclined backwards.-When these grates are so much too wide as to render it necessary to fill them up behind with fire stone, the inclination of the back will be of little confequence; for by making the piece of stone with which the width of the grate is to be diminished in the form of a wedge, or thicker above than below, the front of this stone, which in effect will become the back of the grate, may be made perfectly vertical; and the iron back of the grate being hid in the folid work of the back of the fireplace, will produce no effect whatever; but if the grate be already so narrow as not to admit of any diminution of its width, in that cafe it will be best to take away the iron back of the grate entirely, and fixing the grate firmly in the brick-work, cause the back of the fire-place to ferve as a back to the grate.

Where grates, which are defigned for rooms of a middling fize, are longer than 14 or 15 inches, it will always be best, not merely to diminish their lengths, by filling them up at their two ends with fire-stone, but, forming the back of the chimney of a proper width, without paying any regard to the length of the grate, to carry the covings through the two ends of the grate in such a manner as to conceal them, or at least to conceal the back corners of them in the walls of the covings.

Had these directions been duly attended to by the masons who in Scotland pretend to alter chimneys on the principles of Count Rumford, we should not have observed fo many of the grates placed by thein jutting out beyond the mantle of the chinney; nor of course heard so many complaints of rooms being rendered more

finoky and the confumption of fuel increased by these Chimnen pretended improvements. But when the grate is not fet in its proper place, when its Aoping iron back is retained, when no pains have been taken to make its ends coincide with the covings of the fire place, when the mantle, instead of having its back rounded off, is a vertical plane of iron cutting the column of smoke which rifes beneath it, and, above all, when the throat of the chimney, instead of four, is made, as we often fee, fourteen inches wide; let it be remembered, that not one of Count Rumford's directions has been followed, and that his principles have as little to do with the construction of fuch a chimney as with the building of the wall of China or the pyramids of Egypt.

To contribute our aid to prevent these blunders for the future, we shall here subjoin the Count's directions for laying out the work; not to instruct masons and bricklayers, to whom we earneftly recommend the fludy of the essay itself (B), which contains much valuable information that we have omitted; but merely to give the country gentleman an opportunity of discovering whether the workmen whom he employs deviates far and needlefsly from the principles which he pretends to follow.

When a chimney is to be altered, after taking away the grate and removing the subbish, first draw a strait line with chalk, or with a lead pencil, upon the hearth, from one jamb to the other, -even with the front of the jambs. The dotted line A B, fig. 3. may reprefent this line.

From the middle c of this line, (A B) another line cd, is to be drawn perpendicular to it, across the hearth,

to the middle d, of the back of the chinney.

A person must now stand upright in the chimney, with his back to the back of the chimney, and hold a plumb line to the middle of the upper part of the breaft of the chimney (d, fig. 1.), or where the canal of the chimney begins to rife perpendicularly; -taking care to place the line above in such a manner that the plumb may fall on the line c d (fig. 3.), drawn on the hearth from the middle of the opening of the chimney in front to the middle of the back, and an affiftant must mark the precise place e, on that line where the plumb falls.

I his being done, and the person in the chimney having quitted his flation, four inches are to be fet off on the line c d, from e, towards d; and the point f, where thefe four inches end, (which must be marked with chalk, or with a pencil), will show how far the new back

is to be brought forward.

Through f, draw the line g b parallel to the line A B, and this line g b will show the direction of the new back, or the ground line upon which it is to be built. The line of will show the depth of the new fire place; and if it should happen that cf is equal to about one third of the line A B, and if the grate can be accommodated to the fire place inflead of its being necessary to accommodate the fire-place to the grate; in that case, half the length of the line cf is to be set off from f on the line gfh, on one fide to k, and on the other to i, and the line i k will show the ground line of the fore part of the back of the chimney.

In all cases where the width of the opening of the fire-place in front (A B) happens to be not greater, or

⁽B) It costs but two shillings; and he must be a poor bricklayer indeed who cannot afford to pay that sum for instruction in the most important, as well as most difficult, part of his business.

not more than two or three inches greater than three times the width of the new back of the chimney (i k), this opening may be left; and lines drawn from i to A, and from k to B, will show the width and position of the front of the new covings :- but when the opening of the fire-place in front is fill wider, it must be reduced; which is to be done in the following manner:

From c, the middle of the line A B, c a and c b must be set off equal to the width of the back (i k), added to half its width (fi); and lines drawn from i to a, and from k to b, will show the ground plan of the

fronts of the new covings.

When this is done, nothing more will be necessary than to build up the back and covings; and if the fireplace is defigned for burning coals, to fix the grate in its proper place, according to the directions already given.—When the width of the fire place is reduced, the edges of the covings a A and b B are to make a finish with the front of the jambs .- And in general it will be best, not only for the sake of the appearance of the chimney, but for other reasons also, to lower the height of the opening of the fire place whenever its width in front is diminished.

A front view of the chimney, after it has been thus altered, is exhibited in fig. 4. where the under part of the door-way is represented, as closed by the white dot-

ted lines.

When the wall of the chimney in front, measured from the upper part of the breast of the chimney to the front of the mantle, is very thin, it may happen, and especially in chimneys designed for burning wood upon the hearth, or upon dogs, that the depth of the chimney, determining according to the directions here given,

may be too small.

Thus, for example, supposing the wall of the chimney in front, from the upper part of the breaft of the chimney to the front of the mantle, to be only four inches, (which is fometimes the case, particularly in rooms situated near the top of a house), in this case, if we take four inches for the width of the throat, this will give eight inches only for the depth of the fireplace, which would be too little, even were coals to be burnt instead of wood .- In this case (fays the Count) I should increase the depth of the fire-place at the hearth to 12 or 13 inches, and thould build the back perpendicular to the height of the top of the burning fuel (whether it be wood burnt upon the hearth or coals in a grate); and then, floping the back by a gentle inclination forward, bring it to its proper place, that is to fay, perpendicularly under the back part of the throat of the chimney. This flope, (which will bring the back forward four or five inches, or just as much as the depth of the fire-place is increased), though it ought not to be too abrupt, yet it ought to be quite finished at the height of eight or ten inches above the fire, otherwife it may perhaps cause the chimney to smoke; but when it is very near the fire, the heat of the fire will enable the current of rifing fmoke to overcome the obstacle which this slope will oppose to its ascent, which it could not do so easily were the slope fituated at a greater distance from the burning fuel.

Fig. 5, 6, and 7, show a plan, elevation, and section of a fire-place constructed or altered upon this principle. -The wall of the chimney in front at a, fig. 7. being

only four inches thick, four inches more added to it for Chimney. the width of the throat would have left the depth of the fire-place measured upon the hearth b c only eight inches, which would have been too little; - a niche c and e was therefore made in the new back of the fireplace for receiving the grate, which niche was fix inches deep in the centre of it, below 13 inches wide, (or equal in width to the grate,) and 23 inches high; finishing above with a semicircular arch, which, in its highest part, role seven inches above the upper part of the grate. - The door-way for the chimney-fweeper, which begins just above the top of the niche, may be seen distinctly in both the figures 6 and 7.— The space marked g, fig. 7. behind this door way, may either be filled with loofe bricks, or may be left void .- The manner in which the piece of stone f, fig. 7. which is put under the mantle of the chimney to reduce the height of the opening of the fire place, is rounded off on the infide in order to give a fair run to the column of smoke in its ascent through the throat of the chimney, is clearly expressed in this figure. The plan fig. 5. and elevation fig. 6. show how much the width of the opening of the fire-place in front is diminished, and how the covings in the new fire-place are formed.

A perfect idea of the form and dimension of the fireplace in its original state, as also after its alteration, may

be liad by a careful inspection of these figures. In chimneys, like that represented in figure 8, where the jambs A and B project far into the room, and where the front edge of the marble flab o, which forms the coving, does not come fo far forward as the front of the jambs, the workmen in conftructing the new covings are very apt to place them, -not in the line c A, which they ought to do, -but in the line co, which is a great fault .- The covings of a chimney should never range behind the front of the jambs, however those jambs may project into the room; -but it is not absolutely necessary that the covings should make a finish with the internal front corners of the jambs, or that they should be continued from the back c, quite to the front of the jambs at A .- They may finish in front at a and b; and small corners A, o, a, may be left for placing the shovels, tongs, &c.

Were the new coving to range with the front edge of the old coving o, the obliquity of the new coving would commonly be too great; - or the angle d c o. would exceed 135 degrees, which it never should do,or at least never by more than a very few degrees. No inconvenience of any importance will arise from making the obliquity of the covings lefs than what is here recommended; but many cannot fail to be produced by

making it much greater.

These extracts, which we have made so liberally from Count Rumford's essay on chimney fire-places, will be fufficient, we hope, to bring fully within the comprehension of those who are acquainted with pneumatics. and pneumatic chemistry the principles on which chimneys and fire places should be constructed; but such as are in a great measure strangers to these sciences will do well to confult the effay itself. With a benevolence which does him honour, the ingenious author has expressed a wish that his doctrines on this important subject may be widely propagated; and to encourage artifts to fludy them, he has declared to the public in general, that " as he does not intend to take out himself,

thimney- or to fuffer others to take out, any patent for any inweepers, vention of his which may be of public utility, all perfons are at full liberty to imitate them, and vend them, for their own emolument, when and where, and in any

way they may think proper."

CHIMNEY Sweepers are a class of men who earn their finbfiftence by clearing chimneys of foot, which occa-fions them to fmoke. While chimneys continued to be built in so simple a manner, and of such a width as they are flill observed to be in old houses, they were so easily cleaned that this fervice could be performed by a fervant with a wifp of straw, or a little brushwood fastened to a rope; but after the flues, in order to fave room, were made narrower, or when several flues were united together, the cleaning of them became fo difficult, that they required boys, or people of small fize, accustomed to that employment. The first chimney sweepers in Germany came from Savoy, Piedmont, and the neighbouring territories. These for a long time were the only countries where the cleaning of chimneys was followed as a trade; and hence Professor Beckmann concludes with great probability, that chimneys were invented in Italy. The Lotharingians, however, undertook the business of chimney-sweeping also; on which account the duke of Lotharingia was styled the imperial firemaster. The first Germans who condescended to clean chimneys were miners; and the chimney-sweepers in that empire still procure their boys from the forest of Hartz, where the greatest mines are wrought. Very lately, and perhaps at present, the greater part of the chimney sweepers in Paris were Savoyards, many of them not above eight years of age, who, for the paltry fum of five fous, which they were obliged to share with their avaricious mafter, would scramble, at the hazard of their lives, through a narrow funnel fifty feet in length, and with their befoms clean it from foot and dirt. At what precise period chimney-sweeping became a trade in England and Scotland, we have not been able to learn; but among us, as well as elfewhere, young boys are employed in this business, who are faid to be very harshly treated by fellows who stole them from the doors of cottages in the country. That children have been sometimes kidnapped by chimney-sweepers, we can have no doubt; but that the practice is frequent, we do not believe. We think however that the business might be wholly abolished; for a narrow funnel might certainly, if not very crooked, be swept by a bundle of straw or brushwood fastened to a rope, as well as one that is wider: and the bricks which separate the contiguous flues we know to be less injured by this method of sweeping, when cautiously gone about, than by sending boys up the chimneys.

On the 4th of July 1796, letters patent were granted to Daniel Davis, of the parish of St Giles Middlefex, for his invention of a machine, by which he propoles to fweep and cleanle chimneys, and extinguish chimneys on fire, without any person going up the same, as is now the practice. The machine consists of an apparatus of rack work, of various lengths, which, by means of a hand turn, is made to ascend the chimney. The lengths of the rack-work are joined together by means of mortices and tenons, with a fpring which holds them fait. In each length is a joint, by which the rack-work will accommodate itself to angles or turns in the flues. To the first or appermost leigh is affixed a brush of hair, or wire, or spunge, or other Com clastic substance, as the occasion may require.

This invention is doubtless well calculated to answer the purpose intended, and may perhaps be the means of diminishing the number of those objects of milery, the

unfortunate chimney-sweepers.

CHINA is an empire of fuch antiquity and extent, the laws and customs of the people are so fingular, and the populouinets of the country fo very great-that it has attracted much of the attention of Europeans ever fince it was visited in the 13th century by Marco Paulo the Venetian traveller. Of fuch a country it would be unpaidonable not to give some account in a work of this nature; but we have not, in truth, much to add to what has been faid of China and the Chinese in the Encyclopædia Britannica Since the article China in that work was published, the court of Pekin has indeed been vifited by an embaffy from Great Britain, and the origin of the people, as well as the antiquity of their empire, has been investigated by Sir William Jones with his usual diligence; but from his memoir, published in the second volume of the Afiatic Researches, and from Sir George Staunton's account of the embaffy, there is not much to be extracted which would be

either amufing or instructive to our readers. We have already observed, from Groher and others, that the Chinese not only lay claim to the highest antiquity, but even contend that their first emperor was the first man. Both these positions are controverted by Sir William Jones, who, though he allows the Chinese empire to be very ancient when compared with the oldest European state, is yet decidedly of opinion that it was not founded at an earlier period than the 12th century before the Christian era; and that the people, so far from being aborigines, are a mixed race of Tartars and Hindoos. He begins his investigation with asking, "Whence came the fingular people who long had governed China, before they were conquered by the Tartars? On this problem (fays he 1) four opinions 1 April have been advanced, and all rather peremptorily afferted fearching than supported by argument and evidence. By a few vol. ii. writers it has been urged, that the Chinese are an original race, who have dwelled for ages, if not from eternity, in the land which they now possess. By others, and chiefly by the missionaries, it is infifted that they iprung from the same stock with the Hebrews and the Arabs. A third affertion is that of the Arabs themfelves, and of M. PAUW, who hold it indubitable, that they were originally Tartars, descending in wild clans from the fleeps of Imaus: And a fourth, at least as dogmatically pronounced as any of the preceding, is that of the Brahmans, who decide, without allowing any appeal from their decision, that the Chinas (for so they are named in Sanferit) were Hindoos of the military cast, who, abandoning theprivileges of their tribe, rambled in different bodies to the north-east of Bengal; and forgetting by degrees the rites and the religion of their ancestors, established separate principalities, which were afterwards united in the plains and valleys which are now possessed by them."

Of these opinions, Sir William having very complete. ly demolished the first three, proceeds to establish the fourth, which he confiders as interesting as well as new in Europe. In the Sanscrit institutes of civil and religious duties, revealed, as the Hindoos believe, by MENU

he fon of Brahma, we find (fays he) the following curious passage: ' Many families of the military class, having gradually abandoned the ordinances of the Veda, and the company of Brahmans, lived in a flate of degradation; as the people of Pundraca and Odra, those of Dravira and Camboja, the Yavanas and Sacas, the Paradas and Pablavas, the CHINAS, and some other nations.' A full comment on this text (continues the prefident) would be superfluous; but fince the tellimouy of the Indian author, who, though not a divine personage, was certainly a very ancient lawyer, moralist, and historian, is direct and positive, disinterested and unsuspected, it would decide the question before us if we could be fure that the word China fignifies a Chinefe." Of this fact Sir William Jones took the very heft methods to be fatisfied. He confulted a number of Pandits feparately, who all affured him that the word China has no other fignification in Sanscrit; that the Chinas of Menu fettled in a fine country to the north-east of Gaur, and to the east of Camarup and Napal; that they had long been, and still are, famed as ingenious artificers; and that they (the Pandits) had themselves seen old Chinese idols, which bore a manifest relation to the primitive religion of India. He then laid before one of the best informed Pandits a map of Asia; and when his own country was pointed out to him, the Pandit immediately placed his finger on the north-western provinces of China, as the place where he faid the Chinas of MENU first established themselves.

In the opinion of Sir William Jones, this is complete evidence that the Chinese are descended from an Indian race; but he does not believe that the Chinese empire, as we now call it, was formed when the laws of MENU were collected; and for his calling this fact in question, he offers reasons, which to us are perfectly fatisfactory. By a diligent and accurate comparison of ancient Sanscrit writings, he has been able to fix the period of the compilation of those laws at between 1000 and 1500 years before Christ; but by the evidence of Confucius himfelf, he proves, that if the Chinefe empire was formed, it could be only in its cradle in the 12th century before our era. In the fecond part of the work, intitled Lun Tu, Confucius declares, that "although he, like other men, could relate, as mere lessons of morality, the histories of the first and second imperial houses, yet, for want of evidence, he could give no certain account of them." Now, says Sir William, if the Chinese themselves do not pretend that any historical monument existed in the age of Confucius preceding the rife of their third dynasty, about 1100 years before the Christian epoch, we may justly conclude, that their empire was then in its infancy, and did not grow to maturity till fome ages afterwards. Nay, he is inclined to bring its origin still lower down. "It was not, lays he, till the eighth century before the birth of our Saviour, that a small kingdom was erected in the province of Shen st, the capital of which stood nearly in the 35th degree of northern latitude, and about five degrees to the west of Sigan. That country and its metropolis were both called Chin; and the dominion of its princes was gradually extended to the east and west. The territory of Chin, to called by the old Hindoos, by the Persians, and by the Chinete, gave its name to a race of emperors, whose tyranny made their memory so unpopular, that the modern inhabitants of China hold the SUPPL. VOL. I. Part II.

word in abhorrence, and speak of themselves as the Chira. people of a milder and more virtuous dynasty: but it is highly probable, that the whole nation descended from the Chinas of MENU, and mixing with the Tartars, by whom the plains of Honan and the more fouthern provinces were thinly inhabited, formed by degrees the race of men whom we now fee in possession of the

noblest empire in Asia."

In fupport of this opinion, which the accomplished author offers as the refult of long and anxious inquiries, he observes, that the Chinese have no ancient monuments from which their origin can be traced, even by plaufible conjecture; that their sciences are wholly exotic; that their mechanic arts have nothing in them which any fet of men, in a country fo highly favoured by nature, might not have discovered and improved; that their philosophy feems yet in fo rude a state as hardly to deserve the appellation; and that their popular religion was imported from India in an age comparatively modern. He then institutes a comparison between the mythology of the Chinese and that of the Hindoos; of which the refult is, that the former people had an ancient system of ceremonies and superstitions which has an apparent affinity with some parts of the oldest Indian worship. "They believed in the agency of genii or tutelary spirits, presiding over the stars and the clouds; over lakes and rivers, mountains, valleys, and woods; over certain regions and towns; over all the elements, of which, like the Hindoos, they reckoned five; and particularly over fire, the most brilliant of them. To those deities they offered victims on high places. And the following passage from one of their facred books, fays Sir William, is very much in the flyle of the Brahmans: 'Even they who perform a facrifice with due reverence, cannot perfectly affure themselvelves that the divine spirits accept their oblations; and far lefs can they, who adore the gods with languor and oscitancy, clearly perceive their facred illapies.' These (continues the president) are imperfect traces indeed, but they are traces of an affinity between the religion of MENU and that of the Chinas, whom he names among the apostates from it; and befides them, we discover many other very fingular marks of relation between the Chinese and the old Hindoos.

"This relation (he thinks) appears in the remarkable period of 432,000, and the cycle of 60 years; in the predilection for the mystical number nine; in many fimilar fasts and great festivals, especially at the solitices and equinoxes; in the obsequies, confishing of rice and fruits offered to the manes of their ancestors; in the dread of dying childless, lest fuch offerings should be intermitted; and perhaps in their common abhorrence of red objects, which the Indians carried to far, that MENU himself, where he allows a Brahman to trade, if he cannot otherwise support life, absolutely forbids his trading in any fort of red cloths, whether linen, or woollen, or made of woven bark. In a word, fays Sir William Jones, all the circumstances which have been mentioned feem to prove (as far as such a question admits proof), that the Chinese and Hindoos were originally the same people; but having been separated near 4000 years, they have retained few throng features of their ancient confanguinity, especially as the Hindoos have preferved their old language and ritual, while the Chinese very soon lost both; and the Hindoos have constantly 3 G .

China. constantly intermarried among themselves, while the Chinese, by a mixture of Tartarian blood from the time of their first establishment, have at length formed a race distinct in appearance both from Indians and Tartars."

Sir George Staunton, who accompanied the Earl of Macartney on his embaffy to the emperor of China, does not indeed directly controvert this reasoning; but overlooking it altogether, gives to the Chinese a much Juigher antiquity than Sir William Jones is inclined to allow them. Taking it for granted that their cycle is their own, and that it is not the offspring of astronomical science, but of repeated observations, he seems to give implicit credit to those annals of the empire which almost every other writer has considered as fabulous.

" Next to the studies which teach the economy of life, the Chinese (says he) value most the history of the events of their own country, which is, to them, the globe; and of the celettial movements which they had an opportunity of observing at the same time." In regard to the former, he tells us, that " from about three centuries before the Christian era the transactions of the Chinese empire have been regularly, and without any intervening chaim, recorded both in official documents and by private contemporary writers. Nowhere had history become so much an object of public attention, and nowhere more the occupation of learned individuals. Every confiderable town throughout the empire was a kind of univerfity, in which degrees were conferred on the proficient in the hiftory and government of the state. Historical works were multiplied throughout. The accounts of recent events were exposed to the correction of the witnesses of the facts, and compilations of former transactions to the criticisms of rival writers." In regard to the latter, the movements of the heavenly bodies, he thinks that in no country are there stronger inducements or better opportunities to watch them than in China; and hence he infers, that the cycle of fixty years is of Chinese formation. "In a climate (fays he) favourable to altronomy, the balance of hours beyond the number of days during which the fun appeared to return opposite to, and to obscure, or to mix among the same fixed stars, might be ascertained in a short time; and occasioned the addition of a day to every fourth year, in order to maintain regularity in the computation of time, in regard to the return of the seasons; but many ages must have past before a period could have been discovered, in which the unequal returns of the sun and moon were so accurately adjusted, that at its termination the new and full moons should return, not only to the fame day, but within an hour and a half of the time they had happened, when the period commenced. The knowledge of fuch a period or cycle could be obtained only by a multiplicity of careful and accurate observations. Many revolutions of those great luminaries must have been completed, and numberless conjunctions have past over, before their returns could be ascertained to happen in the same day, at the end of nineteen years. The small difference of time between the returning periods of this cycle, was partly leffened by the intervention of another of 60 years, or of 720 revolutions of the moon, which, with the fettled intercalation of 22 lunations, were at first supposed to bring a perfect coincidence of the relative positions of the sun and moon: but even according to this period, every new year was made constantly to recede, in a very small degree, which

the Chinese corrected afterwards from time to time. Cla This cycle answered a double purpose, one as an era for chronological reckoning, and the other as a regulating period for a luni-folar year. Each year of the cycle is diffinguished by the union of two characters, taken from fuch an arrangement of an unequal number of words placed in opposite columns, that the same two characters cannot be found again together for fixty years. The first column contains a series of ten words, the other twelve; which last are, in fact, the same that denote the twelve hours or divisions of the day, each being double the European hour. The first word or character of the first series or column of ten words, joined to the first word of the second series or column of twelve, marks the first year of the cycle; and so on until the first series is exhausted, when the eleventh word of the second series, combined with the first of the first series, marks the eleventh year of the cycle; and the twelfth or last of the second series, joined with the second of the first series, serves for denoting the twelfth year. The third of the first series becomes united in regular progression with the first of the second series, to mark the thirteenth year; and proceeding by this rule, the first character in the first and in the second series can. not come again together for fixty years, or nntil the first year of the second cycle. The Christian year 1797 answers to the 54th year of the 68th Chinese cycle, which afcertains its commencement to have been 2277 years before the birth of Christ; unless it be supposed that the official records and public annals of the empire, which bear testimony to it, should all be falsified, and that the cycle when first established should have been antidated; which is indeed as little probable as that the period, for example, of the Olympiads should be afferted to have commenced many ages prior to the first Olympic games."

This is a very politive decision against the opinion of a man whose talents and knowledge of oriental learning were fuch as to give to his opinions on fuch subjects the greatest weight. If the statements and reasonings of Sir George Staunton be accurate, the Chinese empire must have subsisted at least 3000 years before the Christian era; for he says expressly, that many ages must have elapsed before the commencement of that cycle, which, according to him, commenced 2277 years before the birth of Christ. But furely Confucius was as well acquainted with the aucient annals of his own country, and the credibility which is due to them, as any man of the present age, whether Chinese or European; and we have feen, that he confidered none of them as authentic which relate events previous to the 11th century before our era. Even this is by much too early a period at which to rely upon them with implicit confidence, if it be true, as Sir George informs us, that the transactions of the empire have been regularly recorded only from about three centuries before the birth of Christ. With respect to the cycle, there is every probability that it was derived from India, where we know that astronomy has been cultivated as a science from time immemorial, and where, we have shewn in another place, that the commencement of the cycle was actually antedated (fee Philosophy, no g. Encycl.) We have therefore no hesitation in preferring Sir William Jones's opinion of the origin of the Chinese empire to Sir George Staunton's; not merely because we believe

the former of these gentlemen to have been more con- drop the mode of writing practised by their ancestors, China. versant than the latter with Chinese literature, but because we think his reasoning more confistent with itself, and his conclusion more consonant to that outline of chronology, which, as he observes, has been so correctly traced for the last 2000 years, that we must be hardy

sceptics to call it in question.

There is another point very nearly related indeed to this, about which thefe two learned men likewife differ. Sir George Staunton informs us, that "no accounts of a general deluge are mentioned in Chinese hiftory." Sir William Jones, on the other hand, in the discourse already quoted, fays, "I may assure you, aster full inquiry and confideration, that the Chinese, like the Hindoos, believe this earth to have been wholly covered with water, which, in works of undifputed authenticity, they describe as flowing abundantly, then fubfixing, and feparating the higher from the lower age of mankind." To which of these authors shall we give credit? The high antiquity which Sir George Staunton affigns to the Chinese empire, rendered it necessary for the persons from whom he drew his information to get quit by any means of an universal deluge. The lystem of Sir William Jones left him at liberty to admit or reject that event according to evidence; and in addition to the authentic records to which he appeals, he quotes a mythological fable of the Chinese, and another of the Hindoos, which, though he lays not upon them any great stress, appear to us, when compared together, not only to corroborate his opinion respecting the defcent of the Chinese, but likewise to shew that both they and the Hindoos have preserved a traditionary account of the deluge very fimilar to that which is given by Moses. The Chinese fable is this: "The mother of Fo-HI was the daughter of Heaven, furnamed Flowerloving; and as the nymph was walking alone on the brink of a river with a fimilar name, she found herself on a sudden encircled with a rainbow; soon after which the became pregnant, and at the end of twelve years was delivered of a fon, radiant as herfelf, who, among other titles, had that of Sui, or the Star of the Year." In the mythological fystem of the Hindoos, "the nymph ROHINI, who presides over the fourth lunar martion, was the favourite mistrels of Soma or the Moon, among whose numerous epithets we find Cumudanáyaca, or delighting in a species of water flower that blossoms at night. The offspring of ROHINI and SOMA was BUD-HA, regent of a planet; and he married ILA, whose father was preferved in a MIRACULOUS ARK from an universal deluge." 'The learned president shews, that, according to the Brahmans, the Chinese descended from BUDHA; and he mentions a divine personage connected with the Chinese account of the birth of Fo-H1, whose name was NIU-VA. But if all these circumstances be laid together, it will appear, we think, pretty evident, that the two ancient nations have preserved the same tradition of an universal deluge, and that the Chinese RAIN-Bow and NIU VA, with the Indian ARK, point to the flood of NOAH.

To Sir William Jones's derivation of the Chinese from the Hindoos, the state of their written language may occur as an objection; for fince it is certain that alphabetical characters were in use among the Hindoos before the period at which he places the emigration of the Chinas, how, it may be asked, came these people to

and to adopt another so very inconvenient as that which the Chinese have used from the foundation of their empire? The force of this objection, however, will vanish, when it is remembered that the Chinas were of the military cast; that they had gradually abandoned the ordinances of the Veda, and were in confequence degraded; and that they rambled from their native country in small bodies. We do not know that the military cast among the Hindoos was ever much devoted to letters; there is the greatest reason to believe that a degraded cast would neglect them; and it is certain that small bodies of men, wandering in deferts, would have their time and their attention completely occupied in providing for the day that was passing over them. That the Chinas should have forgotten the alphabetical characters of the Hindoos is therefore so far from being an objection to Sir William Jones's account of their defcent from that people, that it is the natural confequence of the manner in which he fays they rambled from Hindostan to the northern provinces of what now consti-

tutes the Chinese empire.

Of the origin of the characters which are used by this fingular people, the illustrious prefident of the Afiatic Society gives the following account from a Chinese writer named Li YANG PING. "The earlieft of them were nothing more than the outlines of visible objects, earthly and celestial; but as things merely intellectual could not be expressed by those figures, the grammarians of China contrived to represent the various operations of the mind by metaphors drawn from the productions of nature. Thus the idea of roughness and of rotundity, of motion and rest, were conveyed to the eye by figns representing a mountain, the sky, a river, and the earth. The figures of the fun, the moon, and the stars, differently combined, stood for smoothness and splendour, for any thing artfully wrought, or woven with delicate workmanship. Extension, growth, increase, and many other qualities, were painted in characters taken from the clouds, from the firmament, and from the vegetable part of the creation. The different ways of moving, agility and flowness, idleness and diligence, were expressed by various infects, birds, fishes, and quadrupeds. In this manner passions and sentiments were traced by the pencii, and ideas not subject to any fense were exhibited to the fight; until by degrees new combinations were invented, new expressions added, the characters deviated imperceptibly from their primitive shape, and the Chinese language became not only clear and forcible, but rich and elegant in the highest degree *."

Of this language, both as it is fpoken and written, Refearches, Sir George staunton has given an account fo clear and moir 13. fcientific, that it will undoubtedly place him high among the most eminent philologists of the 18th century. As there is nothing relating to the Chinese more wonderful than their language, which is very little understood in Europe, we shall lay before our readers a pretty copious abstract of what he says on the subject, referring them for further in ormation to his account of Lord

Macartney's Embassy to China.

" In the Chinese tongue (says Sir George) the founds of feveral letters in most alphabets are utterly unknown, and the organs of a native advanced in life cannot pronounce them. In endeavouring to utter the 3 G 2 founds

founds of B, D, R, and X, for instance, he substitutes fome other founds to which the fame organ has been accustomed; L for R, and, as we have reason to think from some expressions of Sir William Jones's, F for B. The nice distinctions between the tones and accents of words nearly refembling each other in found, but varying much in fense, require a nicety of ear to diffinguish, and of vocal powers to render them exactly. Synonymous words are therefore frequently introduced in Chinese dialogue to prevent any doubt about the intended fense; and if in an intricate discussion any uncertainty should still remain as to the meaning of a particular expression, recourse is had to the ultimate criterion of tracing with the finger in the air, or otherwise, the form of the character, and thus afcertaining at once which was meant to be expressed. In a Chinese sentence there is no marked diffinction of substantives, adjectives, or verbs; nor any accordance of gender, number, and case. A very sew particles denote the past, the prefent, and the future; nor are those auxiliaries employed when the intended time may be otherwise inferred with certainty. A Chinese who means to declare his intention of departing to-morrow, never fays that he will depart to-morrow; because the expression of the morrow is fufficient to ascertain that his departure must be future. The plural number is marked by the addition of a word, without which the fingular always is implied. Neither the memory nor the organs of speech are burthened with the pronunciation of more founds to express ideas than are absolutely necessary to mark their difference. The language is entirely monofyllabic. A fingle fyllable always expresses a complete idea. Each fyllable may be founded by an European confonant preceding a vowel, fometimes followed by a liquid. Such an order of words prevents the harfhness of succeeding conforants founding ill together; and renders the language as foft and harmonious as the Italian is felt to be, from the rarity of confonants, and the frequency of its vowel terminations.

"The names or founds, by which men may be first fupposed to have diffinguished other animals, when occasion offered to designate them in their absence, were attempts at an imitation of the founds peculiar to those beings; and still, in Chinese, the name, for example, of a cat, is a pretty near refemblance of its usual civ. It occurred as naturally to endeavour, in speaking, to imitate the voice, if practicable, as it was in writing to sketch a rude figure of the object of description. It is observable, that the radical words of most languages, separated from the servile letters, which mark their inflections, according to their conjugations or declenfions, are monofyllabic. A part of each radical word is retained in composition to denote the meaning and etymology of the compound, which thus becomes polyfyllabic; but the Chinese grammarians, aware of the inconvenience refulting from the length and complication of founds, confined all their words, however fignificant of combined ideas, to fingle founds; and retained only in writing, some part at least of the form of each character denoting a simple idea, in the compound characters conveying complex ideas."

This is a very plaufible, and perhaps the true, account of the monofyllabic form of the Chinese language; but it is proper to state the different account which is given of this peculiarity by Sir William Jones. "It

has arisen, according to him, from the fingular habits coof the people; for though their common tongue be for mufically accented as to form a kind of recitative, yet it wants those grammatical accents without which all hu. man tongues would appear monofyllabic. Thus Amita, with an accent on the first fyllable, means, in the San. ferit language, immeasurable, and the natives of Bengal pronounce it Omito; but when the religion of BUDDHA. the son of Máya, was carried into China, the people of that country, unable to pronounce the name of their new god, called him For, the fon of Mo YE; and didivided his epithet Amita into three fyllables O-MI-TO, annexing to them certain ideas of their own, and expreffing them in writing by three diffinct fymbols. Hence it is that they have clipped their language into monofyllables, even when the ideas expieffed by them, and the written fymbols for those ideas, are very com-

" In the Chinese language Sir George Staunton informs us that there is a certain order, or fettled fyntax, in the succession of words in the same sentence; a succession fixed by custom, differently in different languages, but founded on no rule or natural order of ideas, as has been fometimes supposed; for though a fentence confilts of feveral ideas, to be rendered by feveral words, these ideas all exist and are connected together in the fame instant; forming a picture or image, every part of which is conceived at once. The formation of Chinese fentences is often the simplest and most artless possible, and fuch as may naturally have occurred at the origin of fociety. To interrogate, for example, is often at least to require the folution of a question, whether the subject of doubt be in a particular way or the contrary; and accordingly a Chinese inquiring about his friends health, will iometimes fay, hou, poo hou? The literal meaning of which words is, "well, not well?" A simple character repeated stands sometimes for more than one of the objects which fingly it denotes, and fometimes for a collective quantity of the fame thing. The character of moo fingly is a tree, repeated is a thicket, and tripled is a forest

" In Chinese there are scarcely fifteen hundred distinct founds. In the written language there are at least eighty thousand characters or different forms of letters, which number divided by the first gives nearly fifty fenses or characters upon an average to every found expressed; a disproportion, however, that gives more the appearance than the reality of equivocation and uncertainty to the oral language of the Chinese.

"The characters of the Chinese language were originally traced, in most instances, with a view to express either real images, or the allegorical figns of ideas: a circle, for example, for the fun, and a crefcent for the moon. A man was represented by an erect figure, with lines to mark the extremities. It was evident that the difficulty and tediousness of imitation will have occasioned foon a change to traits more simple and more quickly traced. Of the entire figure of a man, little more than the lower extremities only continue to be drawn, by two lines forming an angle with each other. A faint resemblance, in some few instances, still remains of the original forms in the present hieroglyphic characters; and the gradation of their changes is traced in feveral Chinese books. Not above half a dozen of the present characters consist each of a single line; but most

different strokes. The form of those characters has not been fo flux as the found of words, as appears in the instance of almost all the countries bordering on the Chinese Sea or Eastern Asia, where the Chinese written, but not the oral language, is understood; in like manner, as one form of Arabic figures to denote numbers, and one set of notes for music, are uniform and intelligible throughout Europe, notwithstanding the variety

of its languages. " A certain order or connection is to be perceived in the arrangement of the written characters of the Chinefe; as if it had been formed originally upon a fystem to take place at once, and not grown up, as other languages, by flow and distant intervals. Upwards of two hundred characters, generally confifting each of a few lines or strokes, are made to mark the principal objects of nature, fomewhat in the manner of Bishop Wilkin's divisions, in his ingenious book on the subject of univerfal language, or real character. These may be confidered as the genera or roots of language, in which every other word or species, in a fystematic fense, is referred to its proper genus. The heart is a genus, of which the representation of a curve line approaches fomewhat to the form of the object; and the fpecies referable to it include all the fentiments, passions, and affections, that agitate the human breast. Each species is accompanied by some mark denoting the genus or heart. Under the genus hand are arranged most trades and manual exercises. Under the genus word every fort of speech, study, writing, understanding, and debate. A horizontal line marks a unit; croffed by another line it stands for ten, as it does in every nation which repeats the units after that number. The five elements, of which the Clinese suppose all bodies in nature to be compounded, form fo many genera, each of which comprehends a great number of species under it. As in every compound character or species, the abridged mark of the genus is difcernible by a fludent of that language, in a little time he is enabled to confult the Chinese dictionary, in which the compound characters or species are arranged under their proper gene-

1a. The characters of thefe genera are placed at the beginning of the dictionary, in an order which, like that of the alphabet, is invariable, and foon becomes familiar to the learner. The species under each genus follow each other, according to the number of frokes of which each confilts, independently of the one or few which ferve to point out the genus. The species wanted is thus foon found out. Its meaning and pronunciation are given through other words in common use; the full of which denotes its fignification and the other its found. When no one common word is found to render exacily the fame found, it is communicated by two words with marks, to inform the inquirer that the confount of the first word and the vowel of the second joined together form the precile found wanted.

"The composition of many of the Chinese characters often displays considerable ingenuity, and serves alfo to give an infight into the opinions and manners of the people. The character expressive of happiness includes abridged marks of land, the fource of their phyfical, and of children that of their moral, enjoyments This character, embellished in a variety of ways, is hung up almost in every house. Sometimes written by the

of them confist of many, and a few of so many as seventy hand of the emperor, it is sent by him as a compliment, which is very highly prized, and fuch as he was pleafed to lend to the embassador.

" Upon the formation, changes, and allusions of compound characters, the Chinese have published many thousand volumes of philological learning. Nowhere does criticism more abound, or is more strict. The introduction or alteration of a character is a ferious undertaking, and feldom fails to meet with opposition. The most ancient writings of the Chinese are still classical amongst them. The language feems in no instance to have been derived from or mixed with any other. The written feems to have followed the oral language foon after the men who spoke it were formed into a regular fociety. Though it is likely that all hieroglyphical languages were originally founded on the principles of imitation, yet in the gradual progress towards arbitrary forms and founds, it is probable that every fociety deviated from the originals in a different manner from the others; and thus for every independent fociety there arofe a feparate hieroglyphic language. As foon as a communication took place between any two of them, each would hear names and founds not common to both; each reciprocally would mark down fuch names in the founds of its own characters, bearing, as hieroglyphics, a different fense. In that instance, confequently, those characters cease to be hieroglyphics, and were merely marks of found. If the foreign founds could not be expressed but by the use of a part of two hieroglyplics, in the manner mentioned to be used fornetimes in Chinefe dictionaries, the two marks joined together become in fact a fyllable. If a frequent intercourfe should take place between communities speaking different languages, the necessity of using hieroglyphics merely as marks of found would frequently recur. The practice would lead imperceptibly to the discovery that, with a few hieroglyphics, every found of the foreign language might be expressed; and the hieroglyphics which answered best this purpose, either as to exactness of found or fimplicity of form, would be felected for this particular ule; and ferving as fo many letters, would form in fact together what is called an alphabet. Thus, the passage from hieroglyphic to alphabetic writing may naturally be traced, without the necessity of having recourse to divine instruction, as some learned men have conjectured, on the ground that the art of writing. by an alphabet is too refined and artificial for untutored

"The Chinese printed character is the same as is used in most manuscripts, and is chiefly formed of straight lines in angular positions, as most letters are in Eastern tongues, especially the Sanscrit; the charasters of which, in some inflances, admit of additions to their original form, producing a modification of the tenfe. A running hand is used by the Chinese only on trivial occasions, or for private notes, or for the ease and expedition of the writer; and differs from the other as much as an European manufcript does from print. There are books with alternate columns of both kinds of writing for their mutual explanation to a learner.

"The principal difficulty in the fludy of Chinese writings ariles from the general exclusion of the auxiliary particles of colloquial language, that fix the relation between indeclinable words, such as are all those of the Chinese language. The judgment must be constantly

exercised by the student, to supply the absence of such Grosser, at 200 millions: but great as this is, when com. Oh to the manners, customs, laws, and opinions of the Chinese, and to the events and local circumstances of the country, to which the allusions of language perpetually refer. If it in general be true, that a language is difficult to be understood in proportion to the distance of the country where it is spoken, and that of him who endeavours to acquire it, because in that proportion the allufions to which language has continually recourse are lefs known to the learner, some idea may be conceived of the oblacles which an European may expect to meet in reading Chinese, not only from the remoteness of situation, but from the difference between him and the native of China in all other respects. The Chinese characters are in fact sketches or abridged figures, and a fentence is often a string of metaphors. The different relations of life are not marked by arbitrary founds, fimply conveying the idea of fuch connection; but the qualities naturally expected to arife out of fuch relations become frequently the name by which they are respectively known. Kindred, for example, of every degree is thus distinguished with a minuteness unknown in other languages. That of China has diffinct characters for every modification known by them of objects in the physical and intellectual world. Abstract terms are no otherwise expresfed by the Chinese than by applying to each the name of the most prominent objects to which it might be applied, which is likewife indeed generally the case of other languages. Among the Latins the abstract idea of virtue, for example, was expressed under the name of valour or ftrength (virtus), being the quality most esteemed among them, as filial piety is confidered to be in China. The words of an alphabetic language being formed of different combinations of letters or elemental parts, each with a distinct found and name, whoever knows and combines these together, may read the words without the least knowledge of their meaning; not so hieroglyphic language, in which each character has indeed a found annexed to it, but which bears no certain relation to the unnamed lines or strokes of which it is compofed. Such character is studied and best learned by becoming acquainted with the idea attached to it; and a dictionary of hieroglyphics is less a vocabulary of the terms of one language with the correspondent terms in another, than an encyclopædia containing explanations of the ideas themselves represented by such hieroglyphics. In fuch fense only can the acquisition of Chinese words be justly said to engross most of the time of men of learning among them. The knowledge of the fciences of the Chinese, however imperfect, and of their most extensive literature, is certainly fufficient to occupy the life of man. Enough, however, of the language is imperceptibly acquired by every native, and may, with diligence, be acquired by foreigners for the ordinary concerns of life; and further improvements must depend on capacity and opportunity."

Next to the fingular structure of the oral and written language of the Chinese, there is perhaps nothing in their history more furprising to a native of Europe than the number of the people, and the means by which they contrive to procure subfiftence, without foreign trade, in a country fo crouded, and at the same time not everywhere of a fertile foil. In the Encyclopædia, the population of this vast empire is stated, from M.

affishance. That judgment must be guided by attention pared with the population of every other extensive country, it appears to be far short of the truth. Sir George Staunton has published a statement, taken from one of the public offices in the capital, and given by a great and respectable manderin to Lord Macartney, in which it is shewn that China Proper contains not fewer than 333 millions of inhabitants As the extent of the country is 1,297,999 square miles, there are of course very near 260 inhabitants to every square mile; and of thete miles a very confiderable proportion confilts of nothing but barren rocks. That this account is accurate there can be little doubt; for the extent of the provinces was afcertained by aftronomical observations, as well as by admeasurement; and the number of individuals is regularly taken in each division of a district by a tythingman, or every tenth mafter of a family. These returns are collected by officers refident fo near as to be capable of correcting any grofs miltake, and are all lodged in the great register of Pekin.

For this excessive population our author satisfactorily accounts. Celibacy, says he, is rare in China, even in the military profession; the marriages are prolific as well as early, and the influence of the patriarchal fyftem, to be explained afterwards, is fuch, that a man's children adds to his wealth. It is reckoned a discredit to be without offspring; and they who have none adopt others, who become theirs exclusively. In case of marriage, should a wife prove barren, a fecond may be elpouled in the lifetime of the first. The opulent, as in most parts of the East, are allowed, without reproach, to keep concubines, of whom the children are confidered as being those of the legitimate wife, and partake in all the rights of legitimacy. " Accidents fometimes of extraordinary drought, and fometimes of excessive inundations, occasionally produce famine in particular provinces, and famine difease; but there are tew drains from moral causes either of emigration or foreign navigation. The number of manutactures, whose occupations are not always favourable to health, whose constant confinement to particular spots, and sometimes in a close or tainted atmosphere, must be injurious, and whose residence in towns exposes them to irregularities, bears but a very small proportion to that of husbandmen in China. In general there feems to be no other bounds to Chinese populousness than those which the necessity of subfistence may put to it. These boundaries are certainly more enlarged than in other countries. The whole furface of the empire is, with trifling exceptions, dedicated to the production of food for man alone. There is no meadow, and very little pasture; nor are fields cultivated in oats, beans, or turnips, for the support of cattle of any kind. Few parks or pleafure grounds are feen, excepting those belonging to the emperor. Little land is taken up for roads, which are few and narrow, the chief communication being by water. There are no commons, or lands suffered to lie waste by the neglect, or the caprice, or for the sport of great proprictors. No arable land lies fallow. The foil, under a hot and fertilizing fun, yields annually, in most instances, double crops, in consequence of adapting the culture to the foil, and of fupplying its defects by mixture with other earths, by manure, by irrigation, by careful and judicious industry of every kind. The labour of man is little diverted from that industry

to minister to the luxuries of the opulent and powerful, or in employments of no real use. Even the foldiers of the Clinese army, except during the short intervals of the guards which they are called to mount, or the exercises, or other occasional services which they perform, are mostly employed in agriculture The quantity of sublistence is increased also, by converting more fpecies of animals and vegetables to that purpo!e than is usual in other countries. And even in the preparation of their food the Chinese have economy and management."

The government of China is despotic; and it is a curious spectacle to behold so large a proportion of the whole human race, connected together in one great fyftem of polity, fubmitting quietly, and through fo confiderable an extent of country, to one great fovereign; and uniform in their laws, their manners, and their language, but differing effentially in each of these respects from every other portion of mankind; and neither defirous of communicating with nor forming any defigns against the rest of the world. To produce such a phenomenon, many causes must be combined; but perhaps the principal are to be found in the patriarchal fystem already mentioned, in the laws and cuftoms of the empire, and in the belief that the emperor is the vicegerent of heaven, and guided in all his actions by divine inspiration.

The patriarchal system is founded upon that filial piety which the philosophers of China have uniformly represented as the greatest of human virtues. These fages, while they fuccessfully inculcated this duty, have left parental affection to its own natural influence; and hence in China parents are less frequently neglected than infants are exposed. 'The laws of the empire, to corroborate the disposition to filial obedience, furnish an opportunity for punishing any breach of it, by leaving a man's offspring entirely within his own power: and hence it is, that with the poor, marriage, as we have faid, is a measure of prudence; because the children, particularly the fons, are bound to maintain their pa-

A Chinese dwelling is generally surrounded by a wall fix or feven feet high. Within this inclosure a whole family, of three generations, with all their respective wives and children, will frequently be found. One fmall room is made to ferve for the individuals of each branch of the family, fleeping in different beds, divided only by mats hanging from the ceiling. One common room is used for eating.

The prevalence of this cuftom, of retaining the feveral branches of a family under the fame roof, is attended with important effects. It renders the younger temperate and orderly in their conduct under the authority and example of the older; and it enables the whole to subfift, like foldiers in a mess, with more economy and advantage. As the venerable patriarch of each habitation prefides over his descendants with the authority of a magiltrate; so the different orders of magistrates are, in their different districts and provinces, looked up to with the veneration due from children to their parents, while the emperor is revered as the grand patriarch of the whole empire.

Another thing which contributes much to the permanency of the government and the internal quiet of the empire is, that in China there is less inequality in the fortunes than in the conditions of men. The ancient

annals of the empire tellify, that for a long period of China. time, the earth, like the other elements of nature, was enjoyed by its inhabitants almost in common. Their country was divided into small equal districts; every district was cultivated conjointly by eight labouring families, which composed each hamlet; and they enjoyed all the profit of their labours, except a certain thare of the produce referved for public expences. It is true, indeed, that after a revolution, deplored in all the Chinese histories, which happened prior to the Christian era, the usurper granted all the lands away to the partners of of his victories, leaving to the cultivators of the foil a fmall pittance only out of the revenue which it yielded. Property in land also became hereditary : but in process of time, the most considerable domains were fubdivided into very moderate parcels by the incceffive distribution of the possessions of every father equally among all his fons; the daughters being always married without dower. It very rarely happened that there was but an only fon to enjoy the whole property of his deceased parents; and it could scarcely be increased by collateral succession.

From the operations of all those causes, there was a constant tendency to level wealth; and few could succeed to fuch an accumulation of it as to render them independent of any efforts of their own for its increase. Besides, wealth alone confers in China but little importance, and no power; nor is property, without office, always perfectly fecure. There is no hereditary dignity, which might accompany, and give it pre-eminence and weight. The delegated authority of government often leans more heavily on the unprotected rich than on the poor, who are less objects of temptation. And it is a common remark among the Chinese, that fortunes, either by being parcelled out to many heirs, or by being loft in commercial speculations, gaming, or extravagance, or extorted by oppreffive mandarines feldom continue to be considerable in the individuals of the fame family beyond the third generation. To afcend again the ladder of ambition, it is necessary, by long and laborious study, to excel in the learning of the country, which alone qualifies for public employments

There are properly but three classes of men in China: men of letters, from whom the mandarines are taken; cultivators of the ground; and mechanics, including merchants. In Pekin alone is conferred the highest degree of literature upon those who, in public examinations, are found most able in the sciences of morality and government as taught in the ancient Chinese writers; with which studies the history of their country is intimately blended. Among fuch graduates all the civil offices in the state are distributed by the emperor; and they compose all the great tribunals of the empire. The candidates for those degrees are such as have succeeded in fimilar examinations in the principal city of each province. Those who have been chosen in the cities of the fecond order, or chief town of every diftrict in the province, are the candidates in the provincial capital. They who fail in the first and second classes have still a claim on subordinate offices, proportioned to the class in which they had succeeded. Those examinations are carried on with great folemnity, and apparent fairness. Military rank is likewise given to those who are found upon competition to excel in the military art, and in warlike exercises. This distribution

of offices contributes greatly to the peace of the empire; for the people chearfully fubmit to the authority of those whom they believe to be placed over them by merit alone, and love that conflitution which brings within the reach of the meanest subject, who has talents and industry, the highest station next to the supreme.

"The great tribunals are fituated, for the fake of convenience, near the fouthern gate of the imperial palace at Pekin. To them accounts of all the transactions of the empire are regularly transmitted. They are councils of reference from the emperor, to whom they report every business of moment, with the motives for the advice which they offer on the occasion. There is a body of doctrine composed from the writings of the earliest ages of the empire, confirmed by subsequent lawgivers and fovereigns, and transmitted from age to age with increasing veneration, which serves as rules to guide the judgement of those tribunals. This doctrine feems, indeed, founded on the broadest basis of universal justice,

and on the purest principles of humanity.

"His Imperial majefty generally conforms to the fuggestions of those tribunals. One tribunal is directed to consider the qualifications of the different mandarines for different offices, and to propole their removal when found incapable or unjust. One has for object the prefervation of the manners or morals of the empire, called by Europeans the tribunal of ceremonies, which it regulates on the maxim, that exterior forms contribute not a little to prevent the breach of moral rules. The most arduous and critical is the tribunal of censors; taking into its confideration the effect of fubfifting laws, the conduct of the other tribunals, of the princes and great officers of state, and even of the emperor himself. There are several subordinate tribunals; such as those of mathematics, of medicine, of public works, of literature and history. The whole is a regular and confistent fystem, established at a very early period, continued with little alterations through every dynasty, and revived after any interruption from the caprice or passions of particular princes. Whatever deviation has been made by the present family on the throne, arises from the admission of as many Tartars as Chinese into every tribunal". The opinions of the former are supposed always to preponderate; and many of them are indeed men of confiderable talents and strength of mind, as well as polished manners. They are, however, in general, fitter for military than civil offices. The hardy education, the rough manners, the active spirit, the wandering disposition, the loose principles, and the irregular conduct, of the Tartar, fit him better for the profession, practice, and pursuits of war, than the calm, regulated, and domestic habits of the Chinese. Warriors feem naturally the offspring of Tartary, as literati are of China; and accordingly, the principal military commands are conferred on natives of the former country, as, with many exceptions indeed, the chief civil offices are on those of the latter.

A military mandarin, who was much with Lord Macartney, and was himfelf a diftinguished officer, afferted, that, "including Tartars, the total of the army in the pay of China amounted to 1,000,000 infantry, and 800,000 cavalry. From the observations made by the embasly in the course of their travels through the empire, of the garrifons in the cities of the feveral oreach other, there appeared nothing unlikely in the calculation of the infantry; but they met few cavalry. If the number mentioned really do exist, a great proportion of them must have been in Tartary, or on some service distant from the route of the embassy.

" Of the troops, especially cavalry, a vast number are Tartars, who have a higher pay than their Chinese sel-low-foldiers. The principal officers of confidence in the army are Tartars also None of either nation are received into the fervice but fuch as are healthy, strong, and fightly. The pay and allowances of a Chinese horseman are three Chinese ounces, heavier than European ounces, and three tenths of an ounce, of filver, and fifteen measures or rations (the weight not mentioned) of rice every lunar month. A Tartar horseman, feven fimilar ounces of filver, and 20 measures of rice for the same period. A Chinese foot soldier has one ounce and fix tenths of an ounce of filver, and ten measures of rice; and a Tartar of the same description has two ounces of filver, and ten measures of rice every lunar month The emperor furnishes the arms, accoutrements, and the upper garment, to all the foldiers. Befide their ordinary pay and allowances, they also receive donations from the emperor on particular occasions; as when they marry, and when they have male children born. On the death of their parents they obtain 'a gift of consolation;' as do their families when the soldiers themselves die.

"The public revenues of China Proper are faid to be little less than 200,000,000 of ounces of filver, which may be equal to about 66,000,000 of pounds fterling; or about three times those of France before the late fubversion. From the produce of the taxes all the civil and military expences, and the incidental and extraordinary charges, are first paid upon the spot out of the treasuries of the respective provinces where such expences are incurred; and the remainder is remitted to the Imperial treasury at Pekin. This surplus amounted, in the year 1792, to the fum of 36,614,328 ounces of filver, or 12,204,776 pounds fterling, according to an account taken in round numbers. In case of insurrections, or other occurrences requiring extraordinary expences, they are generally levied by additional taxes on the provinces adjacent to the scene of action, or connected with the occasion of the expence.

"In the administration of the vast revenue of the state, the opportunities of committing abuses are not often neglected; as may be inferred from the frequent confilcation to the emperor in consequence of such transgresfions. It is indeed affirmed, that much corruption and oppression prevail in most of the public departments, by which confiderable fortunes are acquired, notwith-

flanding the modicity of the public falaries."

With such a standing army and so vast a revenue, it will no longer appear wonderful that one man should govern with despotic sway even the immense multitude of people who inhabit the empire of China, especially trained up as those people are in habits of filial submisfion to their superiors. But there are some circumstances in the system of Chinese policy, not yet mentioned, which contribute perhaps more than even these habits and that power to preferve the stability of the government. The emperor referves to himfelf alone the right of relieving the wants of the poor, produced by famine ders, and of the military posts at small distances from or any other unforeseen calamity. On such occasions

he always comes forward. He orders the public granaries to be opened; remits the taxes to those who are vifited with misfortune; affords affiltance to enable them to retrieve their affairs; and appears to his subjects as standing almost in the place of Providence in their favour. He is perfectly aware by how much a stronger chain he thus maintains his absolute dominion, than the mere dread of punishment would afford. The emperor, to whom the British embassy was sent, shewed himself to jealous of retaining the exclusive privilege of benevolence to his subjects, that he not only rejected, but was offended at, a proposal once made to him by some confiderable merchants, to contribute towards the relief of a fuffering province; whilft he fcrupled not, at the fame time, to accept the donation of a rich widow towards the expences of a war in which he was engaged.

This veneration, excited towards the emperor by his apparent benevolence, is increased by an opinion zealoufly instilled into the people, that he has the faculty of predicting future events of the greatest importance. The Chinese, given up to the dotages of judicial astrology, are firmly perfuaded that eclipfes of the fun and moon have a powerful influence on the operations of nature and the transactions of mankind; and the periods of their occurrence become, of course, objects of attention and folicitude. The government of the country, ever anxious to establish its authority in the general opinion of its superior wisdom and constant care for the welfare of the people, employs the European missionaries at Pekin (for it is doubtful if any one of the natives has fo much science) to calculate eclipses, and then announces them to the people with that folemnity which is fitted to enfure veneration for the superintend. ing power whence such knowledge is immediately derived to them. Eclipses of the finn, in particular, are confidered as omenous of fome general calamity; and as great pains are taken to inspire them with a belief that their prosperity is owing to the wildom and virtues of their fovereign, fo they are tempted to attribute to fome deficiency on his part whatever they think portentous. To this prejudice the emperor finds it prudent to accommodate his conduct. He never ventures on any undertaking of importance at the approach of a folar eclipse, but affects to withdraw himself from the presence of his courtiers, to examine strictly into his late administration of the empire, in order to correct any error, for the commission of which the eclipse may have been an admonition. On these occasions be invites his subjects to give him freely their advice: but it is plain that advice must be offered with great deference to a being for whose admonition the motions of the fun and moon are believed to be regulated; and while fuch notions are implicitly admitted, the person of the Chinese emperor, as well as his authority, must be looked upon by his subjects as something more than human.

SUPPL. VOL. I. Part II.

This is in fact the cafe. He is not only approached in person with testimonies of the utmost respect, but is adored when absent with all the rites and ceremonies which are used by the Chinese in the worship of their divinities. On his birth-day, at the new and full moon, and probably on other festivals, all the mandarines refident in the neighbourhood of any of his numerous palaces affemble about noon, and repairing to the palace, folemnly prostrate themselves nine times before the throne, their foreheads striking the floor each time; whilst incense is burning on tripods on each side of it, and offerings are made, on an altar before it, of tea and fruits to the spirit of the absent emperor. Over the throne are feen the Chinefe characters of glory and perfection; and the name of the Deity is given to the emperor, who is confidered by his votaries as possessing in fome fense the attribute of ubiquity. Mr Barrow, one of the gentlemen of the embassy, was present at Yuenmin-yuen, one of the imperial palaces, when these idolatrous rites of adoration were performed, and he was affured that they took place on that day in all parts of the empire, the proftraters being everywhere attentive to turn their faces towards the capital.

That he who claims adoration in his abfence does not appear on his birth-day to receive the compliments of his subjects, will not surprise the reader. The manner in which that festival is celebrated at the palace, where the emperor happens to be refident, is thus defcribed by Sir George Staunton, who witneffed this more than august ceremony at the palace of Zhe-hal in Tartary. "The princes, tributaries, ambassadors, great officers of state, and principal mandarines, were affembled in a vast hall; and upon particular notice, were introduced into an inner building, bearing, at least, the femblance of a temple. It was chiefly furnished with great instruments of music, among which were sets of cylindrical bells, suspended in a line from ornamented frames of wood, and gradually diminishing in size from one extremity to the other, and also triangular pieces of metal arranged in the same order as the bells. To the found of these instruments a slow and solemn hymn was fung by eunuchs, who had fuch a command of their voices as to refemble the effect of the mufical glaffes at a diltance. The performers were directed, in gliding from one tone to another, by the striking of a shrill and fonorous cymbal; and the judges of music among the gentlemen of the embaffy were much pleafed with their execution. The whole had indeed a grand effect. During the performance, and at particular fignals, nine times repeated, all the persons prostrated themselves nine times, except the ambaffador and his fuite, who made a profound obeifance (A). But he whom it was meant to honour, continued, as if it were in imitation of the Deity, invifible the whole time."

That the awful impression meant to be made upon 3 H

(A) The Chinese court, which considers all other sovereigns as subordinate to their own, exacts from foreign ministers, as well as from natives of the empire, nine prostrations upon their first introduction to the emperor. This demand was made, in the last century, of the Dutch, who instantly complied with it in hopes of obtaining in return fome lucrative advantages; and the confequence was, that their ambaffador was treated with neglect, and dismissed without promise of the smallest favour. It was likewise made of a Russian ambassador in the prefent century; but he would not comply with it, until a regular agreement was made for its return, on a like occasion, to his own sovereign. Lord Macartney, who was repeatedly urged to go through the same abject ceremony, displayed such firmness and address, that after much evasion it was at last announced to him, that his imperial majefty would be fatisfied with the fame form of respectful obedience that the English are in the habit of paying to their own fovereign; and upon these terms his lordship was introduced and graciously received:

China. the minds of men by this apparent worship of a fellow- another; and the majority of the common people of a China mortal might not be too quickly effaced, all scenes of fport and gaiety were postponed to the next day, when a variety of entertainments was exhibited in the prefence of the emperor, furrounded by his court and tri-

butary princes.

Notwithstanding the general veneration of the Chinese for the person and government of their emperor, the mandarines afferted that a fect had for ages subfifted in the country, whose chief principles were founded on an antipathy to monarchy, and who nourished hopes of at last subverting it. Their meetings were held in the utmost fecrecy, and no man avowed any knowledge of them; but a fort of inquisition was faid to be established in order to find them out, and they who were fuspected of fuch fentiments were cut off, or hunted out of fociety. Should the French declaration of the rights of man, which, through the zeal of its authors, has been translated into one of the languages of India, find its way into China (of which the court is faid to be much afraid), it would indeed be a powerful engine in the hands of this fecret fect to fap the foundations of the ancient government. The minds of many of the Chinese are far from fatisfied with their condition, which lays both their persons and their fortunes at the mercy of the mandarines. No private man in China is exempted from corporal punishment, which may be instantly inflicted on him at the nod of a magistrate; and when he has occasion to speak to a great mandarine, he is obliged, by the police of the country, to throw himself on his knees, and in that posture to communicate his business. The mandarine himfelf, on the other hand, lies under the hardship of being frequently responsible for events which he could not controul. Upon the general principle that it is his duty to watch over the morals of the people, he is in many cases considered as a criminal for not preventing crimes which he had not been able to prevent. The mandarines are thus aware of not being guaranteed by good conduct against difgrace; and feeling the chagrin of infecurity, many of them mult doubtlefs be ripe for a revolt. Fear may keep them quiet during the reign of a fovereign possessed of abilities and vigilance; but the maxims which regulate the imperial fuccession are fuch, that a firm confederacy could hardly fail at the death of an emperor to introduce great changes in-to the constitution. The throne of China is neither hereditary nor elective. The choice of a successor is left entirely to the reigning prince, who may exclude, as has been instanced, even his own offspring and famito prevent commotions and fraud, it is no uncommon practice for the emperor, during his lifetime, to declare his fucceffor; for when his fucceffion is fettled by a written testament, the throne is not always filled by him for whom it was destined. The father of the emperor to whom the British embassy was fent, is faid to have obtained possession of the throne by suddealy entering the palace in the last moments of his predecessor, and substituting his own name in a testament intended for the exaltation of another.

to what has been said in the Encyclopædia of the religion of the Chinese, we have here very little to add. Various deities are worshipped in the empire by very different rites and ceremonies; but there is in China no state religion. None is paid, preferred, or encouraged by it. The emperor is of one faith; many of the mandarines of counts by means of an instrument called fwanpan (See

third, which is that of Fo. The men of letters venerate rather than adore Confucius; and meet to honour and celebrate his memory in halls of a fimple but neat construction. The numerous and lower classes of the people are less able than inclined to contribute much towards the erection of large and costly edifices for oublic worship: their attention is almost wholly engaged by their houshold gods; for every house has its altar and its deities.

"No people are, in fast, more superstitious than the common Chinese. Beside the habitual offices of devotion on the part of the priests and females, the temples are particularly frequented by the disciples of Fo previously to any undertaking of importance; whether to marry, or go a journey, or conclude a bargain, or change fituation, or for any other material event in life, it is necessary first to confult the superintendant deity. This is performed by various methods. Some place a parcel of confecrated flicks, differently marked and numbered, which the confultant, kneeling before the altar, shakes in a hollow bamboo, until one of them falls on the ground; its mark is examined, and referred to a correspondent mark in a book which the priest holds open, and fometimes even it is written upon a sheet of paper pasted upon the inside of the temple. Polygonal pieces of wood are by others thrown into the air. Each fide has its particular mark; the fide that is uppermost when fallen on the floor is in like manner referred to its correspondent mark in the book or sheet of fate. If the first throw be favourable, the person who made it prostrates himfelf in gratitude, and undertakes afterwards with confidence the bufiness in agitation. But if the throw should be adverse, he tries a second time, and the third throw determines, at any rate, the queftion. In other respects, the people of the present day feem to pay little attention to their priefts. The temples are, however, always open for fuch as choose to confult the decrees of heaven. They return thanks when the oracle proves propitious to their wishes. Yet they oftener cast lots to know the issue of a projected enterprise than supplicate for its being favourable; and their worthip confifts more in thankfgiving than in

"The Chincle are feldom faid to carry the objects to be obtained by their devotion beyond the benefits of this life. Yet the religion of Fo professes the doctrine of the transmigration of fouls, and promises happiness to the people on conditions, which were no doubt originally intended to confift in the performance of moral duties; but in lieu of which are too frequently fubitituted those of contributions towards the erection or repair of temples, the maintenance of priests, and a strict attention to particular observances. The neglect of these is anounced as punishable by the fouls of the defaulters passing into the bodies of the meanest animals, in whom the fufferings are to be proportioned to the transgressions committed in the human form."

Though the Chinese artists are very ingenious as mere workmen, there is hardly any thing which deferves the name of science in the whole empire. So little is the study of mathematics cultivated, that there are few shopkeepers in China who can perform the ordinary operations of arithmetic; but cast up their acSWANPAN Encycl.). Though the composition of gunpowder was certainly known in China much earlier than in Europe, and though the Chinese had employed it from the beginning in blafting rocks, and in making a valt variety of fire-works; yet Sir George Staunton feems convinced, that they never thought of the invention of guns till they were taught by the Europeans to

introduce them into their armies.

The state of physic in this vast country is extremly low, being nowhere taught in public schools or colleges. "A young man who wishes to become a physician, has no other way of acquiring medical knowledge than by engaging himself to some practitioner as an apprentice. He has thus the opportunity of feeing his mafter's practice, of vifiting his patients with him, and of learning fuch parts of his knowledge and fecrets as the other chooses to communicate to him. The emoluments of the profession feldom exceed the skill of the practitioner. As many copper coin as fcarcely are equal to fixpence fterling is faid to be the usual tee among the people; and perhaps quadruple among the mandarines. Medicine is not divided in China into distinct branches as in most parts of Europe. The same person acts as physicien, furgeon, and apothecary. The furgical part of the protession is still more backward than the others. Amputation; in cases of compound fracture and gangrene, is utterly unknown; and death is the speedy consequence of such accidents. The Chincse method of inoculation, which was introduced into the empire about the beginning of the tenth century of our era, is as follows: When the difease breaks out in any diffrict, the physicians of the place carefully collect a quantity of ripe matter from pultules of the proper fort; which being dried and pulverifed, is closely shut up in a porcelain jar, so as to exclude from it the atmospheric air; and in this manner it will retain its properties for many years. When the patient has been duly prepared by medicines, generally of an aperient kind, and strictly dieted for a short time, a lucky day is chosen to sprinkle a little of the variolus powder upon a small piecc of fine cotton wool, and to insert it into the nostrils of the patient.

"No male physician is allowed to attend a pregnant woman, and still less to practife midwifery; in the indelicy of which both fexes feem to agree in China. There are books written on that art for the use of female practitioners, with drawings of the state and position of the infant at different periods of gestation; together with a variety of directions and prescriptions for every supposed case that may take place: the whole mixed with a number of fuper aitious observances.

Many practitioners of physic take the advantage, as elfewhere, of the obscurity in which that art is involved, and of the ignorance and credulity of the people, to gain money by the sale of nostrums and secrets of their own. They distribute hand bills, setting forth the efficacy of their medicines, with attefted cures annexed to them. And there is one feet which boldly arrogates to itself the possession of a medical secret not to die! To those who had all the enjoyments of this life, there remained unaccomplished no other wish than that of remaining for ever in it. And accordingly feveral fovereigns of China have been known to cherish the idea of the possibility of such a medicine. They had put themselves, in full health, under the care of those religious empirics, and took large draughts of the Chinese boafted beverage of immortality. The composition did not confift of merely harmless ingredients; but probably of fuch extracts and proportions of the poppy, and of other fubstances and liquors, as occasioning a temporary exaltation of the imagination, passed for an indication of its vivifying effects. Thus encouraged, they had recourse to frequent repetitions of the dose, which brought on quickly languor and debility of fpirits; and the deluded patients often became victims to deceit and folly in the flower of their age.

"There are in China no professors of the sciences connected with medicine. The human body is never, un-less privately, diffected there. Books, indeed, with drawings of its internal ftructure are fometimes published; but these are extremely imperfect, and consulted, perhaps, oftener to find out the name of the spirit under whose protection each particular part is placed, than

for observing its form and fituation.

"It is a matter of doubt, whether natural history, natural philosophy, or chemistry, be, as sciences, much more improved than anatomy in China. There are feveral treatifes, indeed, on particular fubjects in each. The Chinese likewise possess a very voluminous Encyclopædia, containing many facts and observations relative to them; but from the few refearches which the gentlemen of the embaffy had leifure or opportunity to make during their short visit to the country, they perceived no traces of any general fystem or doctrine by which separate facts or observations were connected and compared, or the common properties of bodies afcertained by experiment; or where kindred arts were conducted on fimilar views, or rules framed, or deductions drawn from analogy, or principles laid down to constitute a science."

Of all people the Chinese are perhaps the most eager in their curiofity about foreigners coming among them, and the most indifferent about the countries of such toreigners. They have been always in the habit of confining their ideas to their own country, emphatically ftyled the middle kingdom. No Chinese ever thinks of quitting it, except a few of desperate fortunes residing near the fea-coast, or fea-faring men, who form a class, in a great measure, apart from society. Even foreign commodities confumed in China remind them only of Canton, whence they received them, as if produced in it; and these commodities they consider, perhaps properly, as of no real benefit to the empire. Regions out of Asia are scarcely mentioned in their books, or noticed in their distorted maps; and the great body of the people would be little gratified with accounts of fuch regions, which did not contain tales of wonders not performed at home, or of powers exerted beyond the ordinary boundaries of nature.

CHINESE PUMP. See Pump in this Supplement. CHINESE WEIGHTS are fo very different in many respects from those in use elsewhere, that it will at least gratify the curiofity of our readers to take some notice of them in this Work. Of these weights Charles Coquebert has presented a specimen to the Philomathema. tical Society in Paris. They are made of copper, and bear a great refemblance in form to the body of a violin. Like that instrument, they are rounded off at the extremities, and indented on the fides to admit the fingers. The faces are flat and parallel, and have Chinese 3 H 2 characters

They ad-Chinese. characters engraven on the upper surface. vance in a regular decimal progression, of which Coquebert has discovered four distinct series, the units of which are in the proportion of 1, 10, 100, 1000. Instead of employing a combination of one, two, four, and eight units, or after the new system of one, two, and five units, the Chinese have a distinct weight for every intermediate number between one and ten. Thus they have weights of 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 20, 30, 40, 50, 60, 70, 80, 90, &c. Of course, those weights which stand related to each other in the proportion of 6 to 7, 7 to 8, 8 to 9, 9 to 10, differ fo little in fize, that it would be impossible to distinguish them without the help of the characters which are engraven upon the face. This is confessedly a defect in the fystem. Of the four different series exhibited to the fociety, the highest bears in China the name of kin, and is nearly of equal value with a pound avoirdupois. The kin contains ten times the number of units of the next inferior weight, which the Chinese denominate leang or loam, and which the Europeans call tael, taille, or Chinese ounce. This ounce is divided into ten then, which answers nearly to our drachm. The then is The Chinese extend the again subdivided into ten fen. decimal subdivision of their weights considerably farther. They have distinct names, which are all monofyllabic, for nine feries below the fen. Supposing the kin to stand for unity, they have,

The Chinese weights, compared with the greatest precision, and with the help of the best instruments. bear the following proportion to our weights: The kin is equal to one pound 12 ounces 2 drachms 24 grains; the leang one ounce one drachm 60 grains; the then 70 grains \$\frac{8}{70}\$; the fen 7 grains \$\frac{8}{100}\$. Confequently the last of this feries, the sun, amounts to no more than o grains 00000000708.

CHINESE Wheel is an engine employed in the province of Kiang-fee, and probably through the whole empire, for raising water from rivers to irrigate plantations of fugar canes, on a fandy foil, confiderably elevated above the level of the river. By Sir George Staunton, who fays that it is ingenious in its contrivance, cheap in its materials, eafy in its operation, and effectual to its pur-

pose, it is thus described:

"I'wo hard wood-posts or uprights are firmly fixed in the bed of the river, in a line perpendicular to its bank. These posts support the axis, about ten feet in length, of a large and durable wheel, confifting of two unequal rims, the diameter of one of which, closelt to the bank, being about fifteen inches shorter than that of the outer rim; but both dipping in the fiream, while the opposite segment of the wheel rifes above the elevated bank. This double wheel is connected with the axis, and is supported by 16 or 18 spokes obliquely inferted near each extremity of the axis, and croffing each other at about two-thirds of their length. They are there strengthened by a concentric circle, and fastened afterwards to the rims: the spokes inserted in the interior extremity of the axis reaching the outer rim, and those proceeding from the exterior extremity of the fame axis, reaching the inner and fmaller rim. Between the rims and the croffing of the spokes is woven a kind

of close basket-work, serving as laddle-boards or floats, Chinese, which meeting fuccessively the current of the stream, obey its impulse, and turn round the wheel. To both its rims are attached small tubes or spouts of wood, with an inclination of about 25 degrees to the horizon, or to the axis of the wheel. The tubes are closed at their outer extremity, and open at the opposite end. By this position, the tubes which happen in the motion of the wheel to be in the stream with their mouths or open ends uppermost, fill with water. As that fegment of the wheel lifes, the mouths of the tubes attach to it, alter their relative inclination, but not fo much as to let their contents flow out till fuch fegment of the wheel becomes the top. The mouths of those tubes are then relatively depressed, and pour the water into a wide trough placed on posts, from whence it is conveyed as may be wanted among the canes.

"The only materials employed in the construction of this water-wheel, except the nave or axis, and the posts on which it rests, are afforded by the bamboo. The rims, the spokes, the ladle boards or floats, and the tubes or spouts, and even the cords, are made of entire lengths, or fingle joints, or large pieces, or thin flices, of the bamboo. Neither nails, nor pins, nor ferews, nor any kind of metal enters into its construction. The parts are bound together firmly by cordage, also of slit bamboo. Thus, at a very trisling expence, is constructed a machine which, without labour or attendance, will furnish, from a considerable depth. a refervoir with a constant supply of water adequate to

every agricultural purpote.

"These wheels are from 20 to 40 feet in diameter, according to the height of the bank and consequent elevation to which the water is to be raifed. Such a wheel is capable of fuftaining with ease 20 tubes or fpouts, of the length of four feet, and diameter two inches in the clear. The contents of fuch a tube would be equal to fix-tenths of a gallon, and a periphery of 20 tubes, twelve gallons. A stream of a moderate velocity would be fufficient to turn the wheel at the rate of four revolutions in one minnte, by which would be lifted 48 gallons of water in that short period; in one hour, 1880 gallons; and 69120 gallons, or upwards of 300 tons of water, in a day."

Sir George, who faw this wheel in motion, thinks it preferable in many respects to any machine yet in use for similar purposes. He observes, that, while it approaches near to the Persian wheel, of which a description and figure is given in the article Hydrostatics (Encycl.), it is more simple than that wheel in its contrivance, and much less expensive. This is indeed true: but the simplest engine of the kind, and therefore the best that has yet been invented, is perhaps that which is employed to throw water into the moss of Blair Drummond in Perthshire. See Moss, Encycl.

CHOPINE, CHOPPINE, or CHOPEENE, a high shoe, or rather clog, worn 200 years ago by the Ita-

Tom Coryat, in his Crudities 1611, p. 262, calls them chapineys, and gives the following account of them: "There is one thing used of the Venetian women and some others dwelling in the cities and townes subject to the figniory of Venice, that is not to be observed, I thinke, amongst any other women in Christendome, which is fo common in Venice, that no women whatfoever goeth without it, either in her house or abroad,

429

colors, fome with white, fome redde, fome yellow. It is called a chapincy, which they wear under their shoes. Many of them are curiously painted; some also of them I have feen fairely gilt; fo uncomely a thing, in my opinion, that it is pitty this foolish custom is not cleane banished and exterminated out of the citie. There are many of these chapineys of a great height, even half a yard high, which maketh many of their women that are very short seeme much taller than the tallest women we have in England. Alfo I have heard it observed among them, that by how much the nobler a woman is, by fo much the higher are her chapineys. All their gentlewomen, and most of their wives and widowes that are of any wealth, are affifted eyther by men or women when they walke abroad, to the end they may not fall. They are borne up most commonly by the left arme, otherwise they might quickly take a fall."

CHOWDRY, in Bengal, the possessor of several Talooks. It is also used as fynonymous with Talookdar, anciently a collector. See TALOOK in this Supplement.

CHRISOM was not, as is faid in the Encyclopædia, a face-cloth or piece of linen laid over the child's head when it was baptized; but it was a white vefture or garment, which, immediately after it was baptized, the priest put upon it, faying, "Take this white vesture as a token of the innocency which, by God's grace in this holy facrament of baptilm, is given unto thee, and for a fign whereby thou art admonished, so long as thou livest, to give thyself to innocence of living, that after this transitory life thou mayest be partaker of life everlasting. Amen."

As foon as the priest had pronounced these words, he anointed the infant upon the head, faying, "Al. mighty God, the Father of our Lord Jesus Christ, who hath regenerated thee by water and the Holy. Ghost, and hath given unto thee the remission of all thy fins; he vouchfafe to anoint thee with the unction of his Holy Spirit, and bring thee to the inheritance of ever-

lafting life. Amen."

It was from this anointing or chrism that the white garment got the name of chrison, which, after being worn a few days, was offered to the priest to be kept in the church or vestry, in order to be produced as evidence against the person whose chrisom it was, should he afterwards deny the faith in which he had been baptized. These ceremonies were retained, for tome time after the reformation, in the church of England, which ordered the mother of the child (if the child was then alive, to offer, when she was chu ched, the chrisom and other accustomed offerings. It the child died before its mother was churched, the chrison was not given to the priest, but employed as a shroud, in which the body was buried; and hence it is that chrisoms are now enumerated, most absurdly indeed, in the weekly bills of mortality. We fay abfurdly; because children who die unbaptized are called chrisoms, though the chrifom, when it was used, was never put on till baptilm. See Whithy on the Book of Common Prayer, &c. CHRONOLOGICAL CHARACTERS are characters

by which times are diffinguished. Of these some are natural or aftronomical; others, artificial or niftorical. The natural characters are fuch as depend on the motions of the stars or luminaries, as eclipses, folflices, equi-

one by a thing made of wood and covered with leather of fundry noxes, the different aspects of the planets, &c. The ar- Chronotificial characters are those that have been invented and established by men; as the folar cycle, the lunar cycle, Church. &c. Historical chronological characters are those supported by the testimony of historians, when they fix the dates of certain events to certain periods. Hutton's Mathematical Dictionary.

CHRONOSCOPE, a word fometimes used to denote a pendulum or machine to measure time.

CHUCKIAH, in Bengal, the jurisdiction of a Fo-

gedar. See FOGEDAR in this Supplement.

CHURCH is a word which has many different fignifications, all fufficiently explained in the Encyclopædia Britannica, where there is likewise given a concise history of the Christian church (fee HISTORY, Sect. ii.), defective, indeed, but perhaps not more fo than was to be expected from the limits of the work and the extent of the subject.

Of the constitution of the primitive and apostolical church, no man can have a correct notion who has not taken the trouble to confult the primitive and apostolical writers; for, as we have elfewhere observed, all modern compilers of ecclehaftical history are more or lefs prejudiced in behalf of the particular church to which they belong, and wrest the language of the original writers fo as to make them hear witness to the antiquity of modes of faith and ecclefiaftical polity, which are not

perhaps a hundred years old.

On this account we shall not here attempt to correct what we really think the mistakes of him who compiled the section of ecclesiastical history in the Encyclopædia. Mosheim and Sir Peter King, whom he seems to have implicitly followed, were indeed great men; and it would be folly to deny that the History of the former, and the Inquiry of the latter, into the constitution of the Primitive Church, are works of learning and ingenuity; but it is not perhaps too much to fay, that both authors wrote under the influence of prejudice. Our readers will discover how closely either the one or the other has adhered to truth, by studying the ecclesiastical writers of the first four centuries. Such a fludy will make them acquainted with the doctrines, discipline, and worfhip of the church before it was incorporated with the flate; and we know not that kind of knowledge which is of more importance to the divine, however much it may be despited in this age of affected science and real ignorance.

Of the principal churches at prefent existing, a pretty full account is given in the Encyclopædia, either under their different denominations, or under the titles of those tenets by which they are chiefly diffinguished; fo that from that Work alone a reader may form a tolerably accurate notion of the faith, worship, constitution, and discipline of the church of Rome, the churches of England and Scotland, the Lutheran and Calvinitical churches on the continent of Europe, as well as of the various fects which have arifen in these kingdoms during the course of the last and present centuries. There is, however, one church which boafts of a very high antiquity, and is certainly spread over a larger extent of country than all the other churches that we have mentioned, of which the account given in the Encyclopædia is exceedingly derective. Our readers will perceive

that the church to which we aliude is

Church. church.

fom (A) a confiderable part of Greece, the Grecian which, according to them, prohibits only the worship-The Greek isles, Wallachia, Moldavia, Egypt, Abyflinia, Nubia, ping of fuch idols as the Gentules believed to be gods; stine, which are all under the jurisdiction of the patri- cers of Christ and the saints, have written on each of archs of Constantinople, Alexandria, Antioch, and Jerusalem. If to these we add the whole of the Russian empire in Europe, great part of Siberia in Afia, Aftracan, Cafan, and Georgia-it will be evident that the Greek church has a wider extent of territory than the Latin, with all the branches which have fprung from it; and that it is with great impropriety that the church of Rome is called by her members the catholic or univerfal church. That in these widely distant countries the professors of Christianity are agreed in every minute article of belief, it would be rash to affert; but there is certainly fuch an agreement among them with respect both to faith and to discipline, that they mutually hold communion with each other, and are in fact but one

The faith of that church.

As the Greek church has no public or established articles, like those of the churches of England and Scotland, we can collect what is its doctrine only from its creeds, from the councils whose decrees it receives (B), from the different offices in its liturgies, and from the catechisms which it authorises to be taught. "The doctrine of the Trinity, and the articles of the Nicene and Athanasian creeds, are received by the Greeks in common with other Christians. In one particular, indeed, they differ from the other churches of Europe, whether Romish or reformed. They believe, that the Holy Spirit proceeds from the Father only, and not from the Father and the Son; and in defence of this opinion they appeal to ecclefiastical history, the acts of councils, the writings of the fathers, ancient manufcripts, and especially to a copy of the creed of Constantinople, engraven on two tables of filver, and hung up in the church of St Peter at Rome by order of Leo III. Of the Nicene or Constantinopolitan creed, therefore, as it is received by them, the eighth article runs in these words; 'I believe in the Holy Ghost, the Lord and Giver of life, who proceedeth from the FA-† Dalla- THER, and with the Father and the Son together is way's Con- worshipped and glorified: And the corresponding arflantinuple, ticle of the Athanafian creed is of course, "The Holy Ancient and Ghost is of the FATHER, neither made, nor created, nor

Modern, and King's begotten, but proceeding †."

Though the bishops and clergy of the Greek clurch remonies, & abhor the use of images, which they pretend to be one It admits of cause of their separation from the see of Rome, they admit into their churches the pictures of faints to instruct. but not of they fay, the ignorant, and to animate the devotion of graven others. This practice they confider as by no means images.

The Greek CHURCH, which comprehends in its bo- contrary to the fecond commandment of the decalogue, Church Lybia, Arabia, Mcsopotamia, Syria, Cilicia, and Pale- whereas their pictures, being used merely as remembranthem the name of the person whom it is meant to represent. Dr King affures us that the more learned of the Ruffian clergy would willingly allow no representa-tion whatever of God the Father; and that, during the reign of Peter the Great, the fynod not only censured the use of such pictures in churches, but petitioned the emperor that they might be everywhere taken down. Peter, however, though he fully concurred in opinion with the fynod, thought this a measure for which the minds of his fubjects were not ripe, and dreaded, that if carried into execution it would occasion a general infurrection. Such pictures, therefore, though not more impious than abfurd, are still in use; and in many churches, as well ancient as modern, the figure of Daniel's Ancient of Days, together with that of Christ and a dove, are painted in one group to fignify the Holy Trinity. Nay, when our author was in St Petersburg, not thirty years ago, there was in the church of St Nicholas the picture of an old man holding a globe, and furrounded with angels, on which GOD THE FATHER was inscribed; and we have not heard that the picture has been fince taken down.

In the Greek as well as in the Roman church, the Invocati invocation of faints is practifed, but they are not invo-of faints ked in either as deities, but merely as intercessors with the Supreme God, "it being more modest (fay the Greeks), as well as more available, to apply to them to intercede with God, than to address ourselves immediately to the Almighty." Plaufible as this reasoning may at first fight appear, it ascribes to the saints the divine attribute of ubiquity, and is likewise in direct contradiction to the doctrine of St Paul, who hath taught us, that as "there is one God, so there is but one mediator between God and man, the man Christ Jesus."

The Greek church, at the celebration of the Lord's Prayers Supper, commemorates the faithful departed, and even the dead prays for the remission of their sins; but she allows not of purgatory, nor pretends to determine dogmatically concerning the state or condition of departed fouls. She must, however, believe that no final judgment is passed upon the great body of mankind (c) till the confirmmation of all things, otherwise such prayers could not be offered without abfurdity; and in this part of her doctrine she is certainly countenanced by all the writers of the primitive church, if not by fome passages of the facred scriptures *. The practice of praying for * Math the dead is loudly condemned in every Protestant coun-xxv. 19. try, and yet there is no Christian who does not in effect -31-

(A) King's Rites and Ceremonies of the Greek Church - Bruce's Travels to the Source of the Nile - and Lobo's Voyage to Abyfinia.

(c) We fay the great body of mankind, because she doubtless believes that Enoch, Elias, and those saints who Jose with our Saviour, have been already judged, and now enjoy their reward in heaven.

⁽B) In the Greek church feven general councils are received, and nine provincial ones. The feven general councils are, 1. The council of Nice, held in the year 325, under Constantine. 2 The first council of Constantinople, held A. D. 381, under Theodofius the Great. 3. The council of Ephelus, A. D. 431, in the reign of Theodofius Minor. 4. The council of Calcedon, A. D. 451, in the reign of Marcian. 5. The fecond council of Calcedon, A. D. 451, in the reign of Marcian. cil of Constantinople, A. D. 553, in the reign of Justinian. 6. The third council of Constantinople in Trull, A. D. 680, in the reign of Constantine Pagonatus. 7. The second council of Nice, A. D. 787.

CHU

pray for his departed friends. This may appear a paradox, but it is an obvious and a certain truth; for where is the man who believes in a general judgment, and does not wish that his deceased wife, or parent, or child, or friend, "may find mercy of the Lord in that day?" Such a wish is the effence of a prayer; which consists not of the founds in which our fentiments are cloathed, but in the aspirations of a devout heart.

Supererogation with its confequent indulgencies and difpensations, which were once so profitable, and afterwards so fatal to the interests of the court of Rome, are utterly disallowed in the Greek church, which likewise lays no claim to the character of infallibility. She is indeed, like some other churches, very inconsistent on this last topic; for whilst she pretends not to an absolute exemption from error, her clergy seem to consider their own particular mode of worship as that which alone is ac-

ceptable to God.

dulin-

Predefination is a dogma of the Greek church, and a very prevailing opinion amongst the people of Russia; "and I must do the justice (fays Dr King) to those who have written upon it, especially the latest authors of that country, to say that they have treated it, as depending on the attribute of prescience in the divine nature, with a much better kind of logic than that with which such points are generally discussed." As our author has not given us the reasoning of the Russian doctors on this difficult subject, we cannot hazard any opinion of our own on the soundness of their logic; but from the state of science in that vast empire, as it was represented to us by an abler judge than he, we doubt of its being entitled to the praise which he bestows on it. (See Russia, n° 104. Encycl.)

In the Greek church there are feven facraments; or, as they are there termed, mysteries, viz. baptism; the chrism, or baptismal unction; the eucharist; consession; ordination; marriage; and the mystery of the holy oil, or euchelaion. By the Greeks a mystery is defined to be "a ceremony or act appointed by God, in which God giveth or fignisheth his grace; and of the seven which they celebrate, sour are to be received by all Christians, viz. baptism, the baptismal unction, the eucharist, and consession. Of these, baptism and the eucharist are deemed the chief; and of the other three, none, not even the euchelaion, is considered as obligatory upon all.

With respect to baptism, we know not that they hold any peculiar opinions. They consider it indeed as so absolutely necessary to salvation, that in cases of extremity, when a priest or deacon cannot be had, it may be administered by a midwife or any other person, and is not to be repeated on any occasion whatever. In this opinion, as well as in the practice founded on it, they are in perfect harmony with the church of Rome, which, as every person knows, has for many ages allowed the validity of lay baptism in cases of necessity. The Portuguese Jesuits, who in the last century visited Abyssinia in the capacity of missionaries, have maintained that, once every year, all grown people are in that country baptized: but Mr Bruce has shown, by the most incontrovertible evidence, that this was a mere fiction, invented to throw odium upon what the church of Rome calls the eastern schism, and abhors perhaps more than paganism itself.

The daily service of the Greek church is so long and so complicated, that it is impossible for us to give an

adequate account of it without swelling this article far beyond its due proportion. Of this the reader will be convinced, when he is informed that the several books Intricate containing the church service for all the days in the and tedious, year, amount to more than twenty volumes in folio, besides one large volume called the regulation, which contains the directions how the rest are to be used.

The four gospels make one volume by themselves; and whenever the gospel is read in any service, the deacon exclaims; "Wisdom, stand up. Let us hear the holy gospel." The priest then faith, "The lesson from the gospel according to St Matthew, St Mark, &c." The deacon says again, "Let us stand." The choir, at the beginning and end of the gospel, always says, "Glory be to thee, O Lord, glory be to thee." From the old testament and the epistles extracts only are used in the service; and when they are to be read, the deacon calls out, "Attend."

The fervice of this church as it now stands, and was at first drawn up in writing, is calculated for the use of monasteries; and when it was afterwards applied to parochial churches, many of the offices or forms, which were composed for different hours of the day and night, were used as one service, without the slightest alteration being made to avoid repetitions. Something of this kind has taken place in the church of England, where the matins, the litany, and the communion, which were formerly three distinct services, read at different times of the day, are now run into one service; which by those not accustomed to it is therefore deemed long, as well as deformed by needless repetitions.

The service of every day, whether it has a vigil or Begins in not, begins in the evening of what we would call the the evenpreceding day, as among the Jews; and for the same ing. reason, because it is said in the Mosaic account of the creation, that " the evening and the morning were the first day." The several services, according to the original or monkish institution, are, I. The vespers, which used to be celebrated a little before sun-set; 2. The after-vespers, answering to the completorium of the Latin church, which used to be celebrated after the monks had fupped, and before they went to bed; 3. The me-Sonyecticon, or midnight service; 4. The matins at break of day, answering to the laudes of the Romish church ; The first hour of prayer, or prima, at sun rise; 6. The third hour, or tertia, at the third hour of the day; 7. The fixth hour, or fexta, at noon; 8. The ninth hour, or nona, in the afternoon at the ninth hour of the day: These are called the canonical hours; but it is to be observed, that the after vespers were not added till a late period, before which the reason assigned for the number of fervices being seven, was, that David saith; " Seven times a day will I praise thee." When all the pfalms and hymns were fung, these daily scrvices could not possibly have been performed in less than twelve or fourteen hours In the church of Russia, and probably in other branches of the Greek church, there are at prefent but three services in the day: the ninth hour, the vespers, and the after-vespers making one; the mesonyetticon, the matins, and prima, another; and the third and fixth hour, with the communion, the last. In all the services, except the communion, prayers and praises are offered to some faint, and to the Virgin Mary, almost as often as to God; and in some of the services, after every fhort prayer uttered by the deacon or the prieft, the

D: fervi of the Mode of

Church.' choir chaunts, "Lord have mercy upon us," thirty,

forty, or fifty times, fucceffively.

Though the number of services is the same every day, the fervices themselves are constantly varying in fome particular or other, as there is not a day which, in the Greek church, is not either a fast or a festival. Befides the faints, whose festivals are marked in the calendar, and who are fo very numerous that there are more than one for every day in the year, there are other faints and feltivals, to which fome portion of the fervice for every day of the week is appropriated. Thus, Sunday is dedicated to the refurrection; Monday, to the angels; Tuesday, to St John Baptist; Wednesday, to the virgin and the cross; Thursday, to the apostles; Friday, to the passion of Christ; and Saturday, to the saints and martyrs. For these days there are particular hymns and fervices, in two volumes folio, to which there is a fupplement containing fervices for the faints and festivals, as they occur in the calendar throughout the year. These different services are mixed together, and adjusted by the directions contained in the book of regulation; and it is the difficulty of this adjustment which makes the public worship of the Greek church so very intricate, that, as was faid of the service of the English church before the Reformation, "there is more business to find out what should be read, than to read it when found out."

We have observed, that the Greeks have no peculiar opinions respecting the nature of baptism; but the rites and ceremonies with which that ordinance is admini Itered will appear to our unlearned readers very extraordinary. On the day that a woman is delivered, the prieft goes to the house, and uses a form of prayer for ingbaptism. her and for the child. On the eighth day the child should be regularly carried to the church, where the priest having figned it with the fign of the cross on the forehead, on the mouth, and on the breaft, offers up for it a prayer, in which he first gives it a name, commonly the name of the faint for that day in the calendar; he then takes it from the midwife, and standing before the picture of the bleffed virgin, he makes the fign of the cross with the infant, uttering a kind of hymn in honour of the Virgin and of Simeon, who held in his bosom the Saviour of our fouls. He then difmisses the company with an exhortation not to delay the baptifing of the infant, should it appear in danger of death before the regular time for its baptism.

On the fortieth day after her delivery, the mother should attend the church to be purified, and carry the child again to be prefented, the person who is to be fponfor being present. Upon their arrival at the church door, the priest utters some pious exclamations; and then, the mother holding the child in her arms and bowing down her head, he makes the fign of the crofs upon her and the child, and laying his hand upon its head he prays, that the woman may be cleanfed from every fin and from every defilement, and that the child may be fanctified and endued with understanding, with wifdom, and with gentleness of manners. He then figns it again, and again prays for it, for its parents, and for its sponsor; after which, if it has been privately baptized, he takes it in his arms, and makes with it the

Greek hymns have Latin defignations?

fign of the crofs before the door of the church, faying, Church " N. N. the fervant of God, enters into the church, in the name of the Father, and of the Son, and of the Holy Ghott, now and for ever, even unto ages of ages. Amen." He then carries the child into the church, faying, " He shall go into thine house, and shall worship toward thy holy temple;" and advancing into the mid-dle of the church, he fays, "In the midft of thy church shall he praise thee." Then, if the child be a boy, he carries him within the rails of the altar; but if a girl, only to the door, and fays " Nunc dimittis (D);" after which he delivers it to the sponsor, who makes three reverences, and retires.

This is called the prefentation of the child in the temple, and can only be performed after it has been baptized. In the detail we have given, we have fuppofed that it was baptized privately before the purification of the mother, which is now indeed commonly the cafe. Such baptism, however, is not regular, being allowed only in cases of necessity; and when it has not taken place, the mother and child are dismissed as soon as fhe is purified, and return at some other time, not fixed, in order that the child may be publicly baptized.

Previous to baptifm, the child, though not two months old, must be solemnly initiated into the church as a catechumen (See CATECHUMEN Encycl.). those whose religion is a reasonable service, such initiation of an infant will be confidered as a very idle ceremony; and the rites with which it is performed are not well calculated to give it even a fictitious importance. At the door of the church the priest unties the girdle of the infant; takes off all his clothes but one loofe garment; turns him towards the east, with his head uncovered, his feet naked, and his hands held down; blows thrice in his face; figns him thrice with the fign of the cross on the forehead and on the breast, and lays his hand upon his head, praying that his "ancient error may be put away from him; that his heart may be filled with faith, hope, and charity; and that he may walk in the ways of God's commandments." The priest then four times exorcises the infant, commanding Satan, in the first exorcism, to "tremble, depart, and flee from Christ's creature, nor dare to return again, nor dare to lurk concealed within him, or to meet him, or to meditate against him, either in the evening or the morning, at midnight, or at noon-day." In the last exorcifm he blows thrice upon the child's mouth, upon his forehead, and upon his breaft; faying, each time, "Drive away from him every evil and unclean spirit that lurks in him, and hath made itself a nest in his heart." The child is now become a catechumen, and, being turned to the west, uncovered, without shoes, and his hands lifted up, the priest repeatedly asks him if he renounces and has renounced the Devil and all his works? and receiving from the sponfor the proper answer, he fays, "Blow and fpit upon him;" and having blown and fpit upon the catechumen, he turns him to the east, and holding down his hands, asks him repeatedly if he be joined to Christ, and if he believes in him? The catechumen or his sponsor replies to each question, that he is, and has been, joined to Christ; and as a proof of

⁽D) We quote the words of Dr King. Is it possible that in the Greek church Latin hymns are used, or that

his faith he repeats, from beginning to end, the Nicene creed. After a repetition of the formerly repeated questions and answers, the priest prays that the catechumen may be called to God's holy fanctification, and

receive the grace of God's holy baptism.

Baptilm may be celebrated immediately after the candidate has been made a catechumen, or on any fubfequent day at no great diffance. In the first part of the form there is not much that is fingular, or with which every scholar is not acquainted. After praying that the water may be fanctified, in terms differing little from those which are used in the most respectable Protestant churches, the priest dips his fingers in it, signs it thrice with the fign of the crofs; and then blowing upon it, fays three times, "Let every adverse power be confounded under the fign of the cross." He then folemnly exorcifes it of the dæmon of darkness and all evil spirits; and prays, that "the person to be baptized therein may put off the old man, which is corrupt after the lust of fraud, and may put on the new man after the image of Him that made him." After this, he blows thrice into a veffel of oil of olives held by the deacon, figns it thrice with the fign of the crofs; and prays fervently, that it may "become to those who are anointed with faith, and are partakers thereof, the unction of incorruption, the armour of righteoufnefs, the renewing of foul and body, for turning afide all machinations of the devil, and for deliverance from all evil." He then fings allelujah thrice with the people, and pours the oil on the top of the water; and making three crosses with it, fays aloud, "Blessed be God, who enlighteneth and fanctifieth every man that cometh into the world, now and forever, even unto ages of ages." The perfon to be baptized is then presented; and the priest, taking some of the oil with two fingers, and making the fign of the crofs on his forehead, on his breaft, and betwixt his shoulders, fays, "N the servant of God is anointed with the oil of gladness, in the name of the Father, and of the Son, and of the Holy Ghoft, now and forever, even unto ages of ages. Amen." He then figns him on the breast and the middle of the back, faying, "For the healing of his foul and body;" then on the ears, faying, "For hearing the faith;" then on the palms of the hands, faying, "Thy hands have made me and fashioned me;" then on the feet, "That he may walk in the way of thy commandments." After the whole body is thus anointed, the priest baptizes him, using the trine immersion; which is unquestionably the most primitive manner. He takes the child in his arms, and holding him upright with his face towards the east, he fays, " IN the fervant of God is baptized (dipping him the first time), in the name of the Father, Amen; in the name of the Son (dipping bim again), Amen; and of the Holy Ghost (dipping him the third time), Amen, now and for ever, even unto ages of ages. Amen." After the baptism, the priest wipes his hands, and with the people sings thrice, from beginning to SUPPL. VOL. I. Part II.

end, the 32d Pfalm; he then puts upon the baptized Church. person a white garment; saying, "N the servant of God is clothed with the garment of righteousness, in the name of the Father, and of the Son, and of the Holy Ghost, now and for ever, even unto ages of ages (E)." He then prays that he may be delivered from the evil one, and all his insidious snares; that he may be confirmed in the true faith; and that he may preserve his soul in purity and righteousness: and proceeds immediately to anoint him with the Holy Chrism.

This chrism is a very different thing from the oil The bapwith which he was anointed previous to baptism, and tilmal chrism, which was used in the confecration of the baptismal water. It can be prepared only by a bishop, and only on one day in the year, viz. Thurfday in Passion week; and as the anointing with it is fubilituted in place of the apostolical rite of laying on hands, called confirmation in the western churches, great quantities of it are of course prepared at once, and distributed through the different churches of each diocefe. The chrism consists of the following ingredients, which in different proportions are all boiled together, and afterwards folemnly consecrated by the bishop: Fine oil (we suppose of olives), white wine, styrax calamita (F), palm-dew, rose-flowers, black palm-gum, Basil-gum, marjoram, thick and thin oil of nutmegs in very different quantities, oil of cinnamon, oil of cloves, lignum Rhodii, oil of oranges, oil of marjoram, oil of lavender, oil of rofemary, effence of rolemary, cedar, black baltam of Peru, fandarac, whitest mastic, and Venice turpentine. With this holy mixture the baptized person is anointed,

the priest making with it the fign of the cross on his

forehead, on his eyes, his nostrils, his mouth, both ears.

his breaft, his hands, and his feet; faying at each part, "The feal of the gift of the Holy Ghost. Amen."

Then with the spoufor and the child he goes thrice

round the font, turning from the right to the left; the

choir, in the mean time, finging, " As many of you as

are baptized unto Christ have put on Christ, allelujah."
Seven days after this ceremony is performed, the child is again brought to the church; when the priest, after praying for him, unties his girdle and linen clothes, washes him with clean water, and, sprinkling him, says, "Thou hast been justified, enlightened, sanctified, in the name of our Lord Jesus Christ, and with the Spirit of our God." Then taking a new sponge moistened with water, he washes his face, breast, &c.; faying, "Thou hast been baptized, enlightened, anointed, sanctified, washed, in the name of the Father, and of the Son, and of the Holy Ghost, now and for ever, even unto ages of ages. Amen."

The last ceremony appended to baptism is that of The tonthe tonsure, or shaving the head of the child in the fore.
form of the cross. At what time this rite crept into
the church it would not be easy to discover. Some
think it received its origin from the religious ceremonics of the Heathen, who certainly rounded the corners

31.

(E) The reader will perceive, that many of these rites and ceremonies are common to the Greek church and the church of Rome in the celebration of the facrament of baptism.

⁽F) We quote the words of Dr King, taking it for granted that our readers will pardon our not giving our-felves much trouble to diffeover, on the prefent occasion, what particular species or variety of the storax he means by this designation. See Styrax, Encycl.

communion-offi.

Church. of their heads, and marred their beards, at a very early period, in honour of their idols (See TheoLogy, no 155. Encycl.); and some pious, but foolish Christians, esteemed it highly commendable to transfer to the true God that worship, in a different form, which had been rendered by their ancestors to false deities. Others will have the tonfure to typify the dedication of the person to the service of God; the cutting off of the hair being always confidered as a mark of fervitude. Be these conjectures as they may, the priest, after the child is baptized, offers up for him several prayers, all alluding to the rite to be performed; and then cuts his hair cross wife, faying, " N the fervant of God is shorn, in the name of the Father, and of the Son, and of the Holy Gholt, now and for ever, even unto ages of ages. Amen."

We have given a full account of the manner in which the facrament of baptifm is celebrated among the Greeks, that the reader may have some notion of the childish superstition of that church, with which certain zealous Protestants in England were very defirous, at the beginning of this century, to form a union. There is no occasion for dwelling so long upon their other of-The Greeks fices. For the celebration of the Lord's Supper they have three have three liturgies that are occasionally used, viz. that of St Chrysostom, which is in ordinary daily use; that of St Basil, used on particular days; and that of the prefandified, as it is called, which is used on the Wedneldays and Fridays during the great fast before Easter. Between the liturgies of St Chrysottom and St Basil there is no effential difference; and the office of the prefanctified is merely a form of dispensing the communion with elements which had been confecrated on the preceding Sunday. We would gladly infert the liturgy of St Chrysostom, or at least such an abstract of it as we have given of the form of adminifering baptism; but as our limits will not permit us to do fo, we must refer fuch of our readers as have any curiofity respecting ful jects of this nature to Dr King's Rites and Ceremonies of the Greek Church.

It is proper, however, to observe here, that many fuperstitious ceremonies have been added to the service fince the age of St Chryfoftom, and that no man can compare his genuine works with the liturgy which now goes under his name, and entertain the smallest doubt but that the latter has been greatly, though gradually, Strange ce- corrupted. In the offertory there is a frange ccremoremony at ny, called the flaying of the Holy Lamb, when the priest, taking into his left hand one of the five loaves which are to be confecrated, thrusts a spear into the right side of it; faying, "He was led as a lamb to the flaughter;" then into the left fide, adding, "And as a blameless lamb before his shearers is dumb, so he openeth not his mouth:" then into the upper part of the loaf; faying, "In his humiliation his judgment was taken away:" and into the lower part; adding, "And who shall de-

clare his generation?" He then thrusts the spear o- Charles bliquely into the loaf, lifting it up, and faying, "For liis life was taken away from the earth." After this he lays down the loaf, and cutting it crosswife, fays, "The Lamb of God, which taketh away the fins of the world, is flain for the life and falvation of the world." All this, and more to the same purpose, is unquestionably modern; but we have no doubt but that the priest uses the words of Chryfoltom himself, when, in the confecration of the elements, he fays, "We offer unto The thee this reasonable, this unbloody facrifice; and we cration implore, we pray thee, we humbly befeech thee, to fend ments down thy Holy Spirit upon us, and those oblations presented unto thee; and make this bread the precious body of thy Christ; and that which is in this cup the precious blood of thy Christ, changing them by thy

Holy Spirit." Dr King observes, that this invocation of the Holy Spirit upon the elements, which in the eastern church is always used after the words of Christ, "This is my body, this is my blood, &c." is inconfishent with the Popish doctrine of transubstantiation: and he is undoubtedly right; for the church of Rome teaches, that the change is made about the middle of the mass, when the prieft, taking into his hand first the bread and then the wine, pronounces over each separately the facred words of confecration; i. e. the words of Christ. "It is the office of the prieft, in this and in all other facraments (lays a dignitary of that church), only to perform the outward fenfible part; but the inward invibble effect is the work of the great God, who accordingly changes the substance of the bread and wine into the body and blood of Christ the very infant that the facred words of confecration are pronounced by the priest over them." But if this be fo, it would be impious, and we believe that by the church of Rome it is deemed impious, to pray afterwards, that God would fend down his Holy Spirit to change into the body and blood of Christ elements which he had already changed into that body and blood, in confequence of the pricit's pronouncing over them the all-powerful words of Christ. Yet is it certain, that in the present Greek church tranfubstantiation is as much an article of faith as in the church of Rome; for now every bishop at his confecration declares, in the most solemn manner, that he believes and "understands that the transubstantiation of Frant the body and blood of Christ, in the holy supper, is ef. stanta fected by the influence and operation of the Holy Ghost, when the bishop or priest invokes God the Father in these words, and make this bread the precious body of thy Christ, &c." This is indeed a different account from that of the Latin church of the time at which this portentous change is wrought; but fuch difference is a matter of very little importance (G). If the change itself be admitted, the consequences must be the fame, whether it be supposed to take place when

the offertory.

> (G) Mr Bruce feems to doubt whether transubstantiation be the doctrine of the Abyssinian church, and relates a conversation which he had on the subject with a priest; who solemnly affirmed, that he never believed in the conversion of the substance of the bread and wine into the substance of our Saviour's body and blood. It must be remembered, however, that the priest had at the time a powerful reason for wishing that doctrine not to be true. The Jesuits uniformly attest, that the Abyssinians believe in the real presence; though it must not be forgotten, that Ludolf was of a different opinion, and that no man had studied the language of Abyssinia more fuccessfully than he.

the priest pronounces the words of institution, or after he has invoked the descent of the Holy Ghost; in either case it leads to idolatry. It may be proper to mention, that in the Greek church it is deemed effential to the validity of this holy facrament, that a little warm water he mixed with the wine; that the napkin, which is spread over the holy table, and answers to the corporale of the church of Rome, be confecrated by a bishop, and that it have some small particles of the rethliques of a martyr mixed in the web, otherwise the eucharift cannot be administered. In this church children may receive the communion immediately after baptism; and the lay communicants, of whatever age, receive both the elements together, the bread being fopped in the cup: The clergy receive them separately.

We have observed, that one of the seven mysteries or facraments of the Greek church is confession; but among the Greeks it is a much more rational and editying fervice than in the church of Rome. In the Greek church the end of confession is the amendment of the penitent; in the church of Rome it is to magnify the glory of the priest In the former church, the confeffors pretend only to abate or remit the penance, declaring the pardon from God alone; in the latter, they take upon them to forgive the fin itself. 'The Greek church prescribes confession sour times in the year to all her members; but the laity, for the most part, confels only once a year previous to receiving the holy communion; and to this they are in Russia obliged by the

laws of the empire.

The ceremonies with which matrimony is performed in the Greek church confift of three diffinct offices, formerly celebrated at different times, after certain intervals, which now make but one fervice. First, there was a folemn service, when the parties betrothed themfelves to each other, by giving and receiving rings or other presents as pledges of their mutual fidelity and attachment. The ancient usage was for the man to receive a gold ring and the woman a filver one, which is still alluded to in the rubric, though, in the present practice, the rings are generally both of gold. At this time the dowry was paid, and certain obligations were entered into to forfeit fums in proportion to it, if either of the parties should refuse to ratify the engagement. At this ceremony, called the unnolgov, or recording of the pledges before witnesses, the priest gives lighted tapers to the parties to be contracted, making the fign of the cross on the forehead of each with the end of the taper before he deliver it.

The fecond ceremony, which is properly the mar-

riage, is called the office of matrimonial coronation, from Church. a fingular circumstance in it, that of crowning the parties. This is done in token of the triumph of continence; and therefore it has, in fome places, been omitted at fecond marriages. Formerly these crowns were garlands made of flowers or flirubs; but now there are kept, in most churches, crowns of filver or some other metal for the celebration of matrimony. At the putting of them on, the priest lays, "N, the fervant of God, is crowned for the handmaid of God;" and " N, handmaid of God, is crowned for the servant of God, in the name of the Father, and of the Son, and of the Holy Ghoft;" adding thrice, "O Lord our God, crown them with glory and honour."

The third ceremony is that of diffolving the crowns on the eighth day; after which the bride is conducted to the bridegroom's house, immediately to enter on the cares of his family.

With respect to discipline and government, the Greek Requiar church bears a striking relemblance to that of Rome, and secular In both there is the same division of the clergy into re-clergy. gular and fecular; the same spiritual jurisdiction of bishops and their officials, and the same distinction of ranks and offices. In some points the discipline of the Greeks differs from that of the Romans. All orders of fecular clergy in the Greek church inferior to bithops are permitted to marry; but celibacy, and the assumption of the monastic habits, are indispensably requisite in those who are candidates for the mitre. The regular clergy, fays Mr Dallaway, are generally men of a certain education; whereas the feculars are of the meaner fort, and illiterate in the extreme.

In the Greek church there are five orders of clergy Five orders promoted by the imposition of hands; but it does not of clergy. appear that the ordination of the reader, or of the fubdeacon, is confidered as a facrament. The forms used in the ordination of deacons, prefbyters, and bishops, are ferious and fignificant (H), bearing in themselves evidence of great antiquity. The candidate for the deaconate or priesthood kneels before the holy table, and the bishop, laying his right hand on his head, faith, "The divine grace, which healeth our infirmities, and Form of supplieth our defects, promoteth N, the most pious fub. ordination, deacon, to the order of deacon;" or, in the case of the priesthood, "The most pious deacon to the order of a presbyter; let us pray for him, that the grace of the Holy Spirit may come upon him." It does not appear, from Dr King's account of these offices, that in the Greek church the attending presbyters lay on their hands together with the bishop at the ordination of a presbyter.

(H) We must except those used in the church of Abyssinia, which, according to Mr Bruce, are shamefully indecent. "A number of men and children present themselves at a distance, and there stand, from humility, not daring to approach the abuna or bishop. He then asks who these are? and they tell him that they want to be deacons. On this, with a small iron cross in his hand, after making two or three signs, he blows with his mouth twice or thrice upon them; faying, Let them be deacons. I faw once (fays our author) all the army of Begemder made deacons, just returned from shedding the blood of 10,000 men. With those were mingled about 1000 women, who consequently having part of the same blast and brandishment of the cross, were as good deacons as the rest. In the ordination of priests a little more ceremony is used; for they must be able to read a chapter of St Mark, which they do in a language of which the abuna understands not one word. They then give him a brick of falt, to the value perhaps of fixpence, for their ordination; which, on account of this present, the Jesuits maintained to be Simoniacal." There is but one bishop or abuna in Abyssinian, and he is always a soreigner, subordinate in his jurisdiction to the patriarch of Alexandria.

Church.

presbyter, as is practifed in the church of England; but feveral bishops lay on their hands together with the archbishop at the confecration of a bishop.

Solemn confecration of bishops.

This is indeed a very folemn cerem uy. The candidate for the episcopate, who is always an archimandrite or hieromonachus, i. e. an abbot or chief monk in fome monastery, being named to the vacant see, and the election being confirmed, repairs, at the time appointed, to the church where the confecration is to be performed. Being arrived, he is introduced by the proto-pope (1) and proto-deacon to the archbishop and bishops, who are arranged in proper order on a temporary theatre or platform erected in the church for the occasion. He there gives an account of his faith; declares folemnly that he has neither given nor promifed money, or any bribe-worthy fervice, for his dignity; and promifes to adhere fleadily to the traditions and canons of the eastern church, to visit his diocese regularly, and to oppose strenuously all innovations and herefies, particularly the errors of the Latin church. This being done. the archbishop fays, "The grace of the Holy Spirit, through my humility, exalts thee N. archimandrite or hieromonachus, beloved of God, to be bishop of the cities N. N. which God preserve." With much ceremony the bishop elect is then conducted from the theatre, within the rails of the holy altar, where he kneels down with the other bishops, who hold open over his head the holy gospel with the letters inverted, the archbishop faying aloud, "The divine grace, which always healeth our infirmities, and supplieth our defects, by my hand conducteth thee N. archimandrite or hieromonachus, beloved of God, bishop elect of the cities of N. N. which God preserve!-Let us pray therefore for him, that the grace of the most Holy Spirit may come upon him." Then the priests say thrice, "Lord have mercy upon us;" and while the bishops continue to hold the gospel, the archbishop signs the newly confecrated bishop thrice with the sign of the cross, saying, "In the name of the Father, and of the Son, and of the Holy Ghost, now and for ever, even unto ages of ages. Amen." Then all the bishops putting their right hands on his head, the archbishop prays that he may be confirmed in the office of which they have judged him worthy, that his priesthood may be rendered irreproachable, and that he himself may be made holy and worthy to be heard of God. After this, one of the affifting bishops reads a short litany in a low voice, to be heard only by those within the altar, and the other bishops make the responses. At the end of the litany the archbishop, laying his hand again upon the head of the newly confecrated bishop, prays in very decent and devout terms, that Christ will render him an imitator of himself, the true shepherd; that he will make him a leader of the blind, a light to those who walk in darkness, and a teacher of infants; that he may shine in the world, and receive at last the great reward prepared for those who contend boldly for the preaching of the gospel. After this the pastoral-staff is delivered to the new bishop, with a very proper and folemn exhortation from the archbishop, to feed the flock of Christ committed to his care.

The last facrament of the Greek church is that of Church the holy oil or euchelaion, which is not confined to perlons periculose agrotantibus, et mortis periculo imminente, like the extreme unction of the Romish church; but is administered, if required, to devoit persons upon the flightest malady. Though this ordinance is derived from St James, chap. v. ver. 14, 15. it is by no means deemed necessary to falvation, or obligatory upon all Christians; and it is well that it is not, for seven priests are required to administer it regularly, and it cannot be administered at all by less than three. The oil is confecrated with much folemnity; after which each priest, in his turn, takes a twig, and dipping it in the oil now made holy, anoints the fick person cross-wife, on the forehead, on the nostrils, on the paps, the mouth, the breast, and both fides of the hands, praying that he may be delivered from the bodily infirmity under which he labours, and raifed up by the grace of Jesus Christ.

In the Greek, as well as in the Latin church, there The lay is a fervice, called the divine lavipedium; observed on the dium. Thursday of passion-week, in imitation of our Saviour's humility. At Constantinople Jesus Christ is, on this occasion, personified by the Patriarch, and everywhere elfe by the bishop of the diocese, and the twelve apostles by twelve regular priefts, when a ludicrous contest arifes who shall represent Judas; for the name attaches for This office is performed at the west end of the church, where an arm chair is fet at the bottom, facing the east, for the bishop; and on each side are placed twelve chairs for the twelve priefts, who are to reprefent the twelve apostles. The prayers and hymns used on this occasion are exceedingly beautiful and appropriate; and when the first gospel, relating our Saviour's washing of his disciples feet, begins to be read, the bishop or patriarch rises up, and takes off his pontifical vestments by himself without assistance. He then girds himself with a towel, and taking a bason of water in his hand, kneels down and washes one foot of each prieft, beginning with the youngest; and after having washed it he kisses it. All this is done as the several circumstances are read; and when he comes to the last priest, who is supposed to represent Peter, that priest rifes up and faith, "Lord, dost thou wash my feet?" &c. The bishop answers in the words of our Saviour; and having finished the whole, puts on his garments a. gain, and fits down; and as the fecond gospel is read (K), repeats the words of our Saviour, " Know ye what I have done unto you?" &c. The office is certainly ancient, and if decently performed must be affecting

Under the word PATRIARCHS (Encycl.) we have The pringiven a fufficient account of the rife of the patriarchates, leged as well as of the various degrees of rank and authority patriar claimed by the bishops of several other sees in the Greek of Conchurch. It may be proper to add here, that after the taking of Constantinople by Mohammed II. he continued to the patriarch of that city the same present which the Greek emperors had been accustomed to make—a pastoral staff, a white horse, and four hundred ducats in gold. To the Greek church and the maintenance of its clergy he left indeed ample revenues, which they have gradually facrificed to their inconstan.

cy,

⁽¹⁾ In the Greek church all parish priests are called papas or popes; and the proto pope is an archpresbyter.
(K) The first gospel is John xiii. 3—12. The second gospel is John xiii. 12—18.

Of th, cy, their ambition, and their private jealoufy. Still, however, the patriarch of Constantinople fills a very lucrative and high office. "Besides the power of nominating the other three patriarchs, and all episcopal dignitaries (fays Mr Dallaway), he enjoys a most extensive jurisdiction, comprising the churches of Anatolia, Greece, Wallachia, Moldavia, and the islands of the Archipelago. Since the close of the fixteenth century, the Russian church has claimed a jurisdiction independent of the see of Constantinople; though appeals have been made to that fee in cales of extraordinary importance. The influence of the patriarch with the Porte is very extensive, as far as his own nation is concerned. His memorials are never denied; and he can, in fact, command the death, the exile, imprisonment for life, deposition from offices, or pecuniary fine, of any Greek whom he may be inclined to punish with rigour, or who has treated his authority with contempt. On the death of the patriarch the most eager competition is exerted to fill the vacant throne; which, as it is obtained by bribery and intrigue, is of course a very unstable feat to the successful candidate, should another offer to accept the appointment at a lower falary." For a fuller account of the doctrines, discipline, and worship of the Greek church at present, we refer the reader to King's Rites and Ceremonies of the Greek Church in Russia, and to Dallaway's Constantinople ancient and modern (published in 1797); from which two works this abstract has been mottly taken.

CHUSAN ISLANDS, a cluster of small islands on the east coast of China, which were visited by Lord Macartney in his course to Pekin. Most of these islands feen to be hills rifing regularly out of the fea, and rounded at top, as if any points or angles existing in their original formation had been gradually worn off into a globular and uniform shape. Many of them, though close to each other, are divided by channels of great depth. They rest upon a foundation of grey or red granite, some part resembling porpliyry, except in hardness. They were, certainly, not formed by the successive alluvion from the earth brought into the sea by the great river at whose mouth they are fituated, like the numerous low and muddy islands at the mouth of the Po, and many others; but should rather be confidered as the remains of part of the continent thus scooped and furrowed, as it were, into islands, by the force of violent torrents carrying off, further into the sea, whatever was less resistible than the rocks just mentioned. Some of them wore a very inviting aspect; one in particular, called Poo-too, is described as a perfeet paradife. This fpot was chosen, no doubt, for its natural beauties, and aiterwards embellished, by a set of religious men, who, to the number of three thousand, possess the whole of it, living there in a state of celibacy. It contains four hundred temples, to each of which are annexed dwelling houses and gardens for the accommodation of those monks. This large monastery, as it may be called, is richly endowed, and its fame is fpread throughout the empire.

The English East India Company had once a factory at Chusan, the principal of these islands, from which they were many years ago interdicted. This, according to the account of a Chinese merchant who remembered the factory, was not occasioned by any offence given by the English, but by the avarice of the officers

governing at Canton, who draw large fums from the Chufin, accumulation of foreign trade in that port. Perhaps, too, the excessive jealousy of the Chinese government might fancy danger in the unreftrained communication between foreigners and the subjects of that empire in feveral of its ports at the same time.

Ting-hai, the chief town of Chusan, resembles Venice, but on a smaller scale. It is surrounded, as well as interfected, by canals, over which are thrown steep bridges, ascended by steps like the Rialto. The streets are narrow, and paved with square flat stones; but the houses, unlike the Venetian buildings, are low and mostly of one story. The ornaments of these buildings are confined chiefly to the roofs, on the ridges of which are uncouth figures of animals in clay, stone, or iron. The town is full of shops, containing chiefly articles of clothing, food, and furniture, displayed to full advantage. Even coffins are painted in a variety of lively and contrasting colours. The smaller quadrupeds, including dogs, intended for food, are exposed alive for fale, as well as poultry, and fish in tubs of water, with eels in fand. When the gentlemen belonging to the embaffy were at Ting-hai, they were struck with the number of places where tin-leaf and flicks of odoriferous wood were fold for burning in the temples, which indicated no slight degree of superstition in the people. Superstition, however, made them not idle; for throughout the whole place there was a quick and active industry. Men passed busily through the streets, while not an individual was feen asking alms; and the women were employed in the shops. At Chusan, the number of valuable harbours, or places of perfect fecurity for thips of any burden, is almost equal to the number of islands. This advantage, together with that of their central fituation, in respect to the eastern cost of China, and the vicinity of Corea, Japan, Leoo-keoo, and Formosa, attract considerable commerce, especially to Ning-poo, a city of great trade in the adjoining province of Che-chiaug, to which all the Chufan islands are annexed. From one port in that province twelve vessels fail annually for copper to Japan.

According to Brookes, Chusan is in N. Lat. 30. 0.

and E. Long. 124. 0.

CINARA, or CYNARA, which we translate artichoke, is, according to Professor Beckmann, the name which was given by the ancients to a plant very different from the artichoke of our kitchen gardens, though he admits that they belong to the fame genus. The proofs which he adduces for the truth of his opinion are too tedious to be introduced into this Work, especially as they appear not to us to be absolutely conclusive. We must therefore refer the reader to his History of Inventions. The cinara, carduus, and fcolymus (fee Scolymus in this Supplement), were in his opinion species of the thiftle, of which the roots and young shoots, as well as the bottom of the calyx of the last, were eaten. He has proved indeed, he thinks, that the Greeks and Romans used the pulpy bottom of the calyx, and the tenderest stalks and young shoots of many plants belonging to the thiftle kind, in the same manner as we use artichokes and cardoons, but that these latter were unknown to them.

" It appears probable (fays he) that the use of these thistles, at least in Italy and Europe in general, was in the course of time laid aside and forgotten, and that the Circular.

Cinnabar artichoke, when it was first brought to Italy from the Levant, was confidered as a new species of food. It is undoubtedly certain that our artichoke was first known in that country in the 15th century. Hermolaus Barbarus, who died in 1494, relates that this plant was first seen at Venice in a garden in 1473, at which time it was very scarce. About the year 1466, one of the family of Strozza brought the first artichokes to Florence from Naples. Politian, in a letter in which he describes the dishes he found at a grand entertainment in Italy in 1488, among these mentions artichokes. They were introduced into France in the beginning of the 16th century, and into England in the reign of Henry VIII."

The original country of the artichoke is unknown. Linnaus fays that it grew wild in Narbonne, Italy, and Sicily, as the cardoon did in Crete; but our author has proved very fufficiently, that with respect to both these facts the great botanist was misinformed. The artichoke is certainly known in Persia; but Tavernier fays expressly, that it was carried thither, like afparagus and other European vegetables of the kitchen garden, by the Carmelite and other monks; and that it was only in later times that it became common.

CINNABAR. See CHEMISTRY in this Supplement,

no or.

CIRCLE OF CURVATURE, or circle of equicurvature, is that circle which has the same curvature with a given curve at a certain point; or that circle whose radius is equal to the radius of curvature of the given curve at that point.

CIRCLES of Declination are great circles interfeeting

each other in the poles of the world.

CIRCLE of Distipation, in optics. See Optics, En-

CIRCLE Equant, in the Ptolemaic aftronomy, is a circle described on the centre of the equant. Its chief use is to find the variation of the first inequality.

CIRCLES of Excursion are little circles parallel to the ecliptic, and at such a distance from it, as that the excursions of the planets towards the poles of the ecliptic may be included within them; being usually fixed at

about 10 degrees.

CIRCLES of Position, are circles passing through the common interfections of the horizon and meridian, and through any degree of the ecliptic, or the centre of any star, or other point in the heavens; and are used for finding out the fituacion or position of any flar. These are usually fix in number, cutting the equinoctial into 12 equal parts, which the aftrologers call the celeftial houses, and hence they are sometimes called circles of the celefical houses.

CIRCULAR LINES, a name given by some authors to fuch straight lines as are divided by means of the divisions made in the arch of a circle; fuch as the fines,

tangents, secants, &c.

CIRCULAR Parts, called, from the use which he first made of them, Napier's circular parts, are the five parts of a right-angled or a quadrantal spherical triangle; they are the two legs, the complement of the hypothenuic, and the complements of the two oblique angles.

Concerning these circular parts, Napier gave a general rule in his Logarithmorum Canonis Descriptio, which is this; "The rectangle under the radius and the fine of the middle part is equal to the rectangle under the

tangents of the adjacent parts, and to the rectangle un- Cire der the colines of the opposite parts. The right angle or quadrantal fide being neglected, the two fides and the complements of the other three natural parts are called the circular parts, as they follow each other as it were in a circular order. Of thefe, any one being fixed upon as the middle part, those next it are the adjacent, and those farthest from it the opposite parts."

This rule contains within itself all the particular rules for the folution of right-angled spherical triangles, and they were thus brought into one general comprehensive theorem, for the fake of the memory; as thus, by charging the memory with this one rule alone: All the cases of right angled spherical triangles may be resolved, and those of oblique ones also, by letting fall a perpendicular, excepting the two cates in which there are given either the three fides, or the three angles. And for these a similar expedient has been devised by Lord Buchan and Dr Minto, which may be thus expressed: " Of the circular parts of an oblique spherical triangle, the rectangle under the tangents of half the fum and half the difference of the fegments at the middle part (formed by a perpendicular drawn from an angle to the opposite side), is equal to the rectangle under the tangents of half the fum and half the difference of the oppolite parts." By the circular parts of an oblique fpherical triangle are meant its three fides and the fupplements of its three angles. Any of these fix being affumed as a middle part, the opposite parts are those two of the same denomination with it, that is, if the middle part is one of the fides, the opposite parts are the other two, and, if the middle part is the supplement of one of the angles, the opposite parts are the supplements of the other two. Since every plane triangle may be confidered as described on the inrface of a sphere of an infinite radius, these two rules may be applied to plane triangles, provided the middle part be restricted to a side.

Thus it appears that two fimple rules suffice for the folution of all the possible cases of plane and spherical triangles. These rules, from their neatness, and the manner in which they are expressed, cannot fail of engraving themselves deeply on the memory of every one who is a little versed in trigonometry. It is a circumftance worthy of notice, that a perion of a very weak memory may carry the whole art of trigonometry in his head.

CIRCULATING DECIMALS. See DECIMALS in

this Supplement.

CLOCK, a machine for measuring time, of which a description is given in the Encyclopædia. For the scientific principles of clock and watch making, as well as for a fhort account of the most valuable constructions,

fee WATCH-Making in this Supplement.

COACH, as we have observed in the Encyclopædia, is a very modern invention, if by that word be meant a covered carriage suspended on springs. We learn, indeed, from the laborious refearches of Professor Beckmann, that coaches of fome kind were known in the beginning of the 16th century; but they were used only by women of the first rank, for the men thought it difgraceful to ride in them. At that period, when the electors and princes did not choose to be present at the meetings of the flates, they excused themselves by informing the emperor that their health would not permit

(ch. them to ride on horseback; and it was confidered as a point established, that it was unbecoming for them to ride like women. It is certain, however, that, about the end of the 15th century, the emperor, kings, and princes, began to employ covered carriages on journeys,

and afterwards on public folemnities.

The wedding carriage of the first wife of the emperor Leopold, who was a Spanish princels, cost, together with the harnefs, 38,000 florins. The coaches used by that emperor are thus described by Kink: " In the imperial coaches no great magnificence was to be feen; they were covered over with red cloth and black nails. The harness was black, and in the whole work there was no gold. The pannels were of glass, and on this account they were called the imperial glass coaches. On festivals the harness was ornamented with red filk fringes. The imperial coaches were diffinguished only by their having leather traces; but the ladies in the imperial fuite were obliged to be contented with carriages, the traces of which were made of ropes." At the magnificent court of Duke Ernest Augustus of Hanover, there were in the year 1681 fifty gilt coaches with fix horses each. So early did Hanover begin to surpass other cities in the number of its carriages. The first time that ambasadors appeared in coaches on a public folemnity was at the imperial commission held at Ersurth in 1613 respecting the effair of Juliers.

In the hiltory of France we find many proofs that at Paris, in the 14th, 15th, and even 16th centuries, the French monarchs rode commonly on horses, the fervants of the court on mules, and the princesses, together with the principal ladies, fometimes on asses. Persons of the first rank often fat behind their equerry, and the horse was often led by fervants. Carriages, however, of fome kind appear to have been nied very early in France. An ordinance of Philip the Fair, issued in 1294 for suppressing huxury, and in which the citizens wives are forbid to use carriages (cars), is still preserved. Under Francis I. or rather about 1550, somewhat later, there were in Paris for the first time only three coaches.

The oldest carriages used by the ladies in England were known under the now forgotten name of whirlicotes. When Richard II. towards the end of the 14th century, was obliged to fly before his rebellious subjects, he and all his followers were on horschack; his mother only, who was indisposed, rode in a carriage. however, became afterwards fomewhat unfashionable, when that monarch's queen, Ann, the daughter of the Emperor Charles IV. flewed the English ladies how gracefully and conveniently she could ride on a sidesaddle. Whirlicotes were laid afide, therefore, except at coronations and other public folemnities. Coaches were first known in England about the year 15%0, and, as Stow fays, were introduced from Germany by Fitzallen, earl of Arundel. In the year 1598, when the English ambassador came to Scotland, he had a coach with him. Anderson places the period when coaches began to be in common use about the year 1605. The celebrated duke of Buckingham, the unworthy favourite of two kings, was the first person who rode with a coach and fix horses, in 1619. To ridicule this new pomp, the earl of Northumberland put eight horses to

Respecting the progress of luxury with regard to coaches, rhe reader will find much curious information in the first volume of Professor Beckmann's History of Cobalt. Inventions. It is perhaps one of the most entertaining articles in that very learned work. The author, however, with all his labour; has not been able to afcertain the country in which coaches hung on fprings were first used; but he seems inclined to give the credit of the invention to Hungary.

COBALT (see CHEMISTRY-Index, in this Supplement), is a valuable article to potters and dyers. To fit it for their use, it is first roasted and freed from the foreign mineral bodies with which it is united: it is then well calcined, and fold either mixed or unmixed with fine fand under the name of zaffer (zaffera); or it is melted with filiceous earth and pot ashes to a kind of blue glass called fmalt, which when ground very fine is known in commerce by the name of powder blue. All these articles, because they are most durable pigments, and those which best withstand fire, and because one can produce with them every shade of blue, are employed above all for tinging cryftal and for enamelling; for counterfeiting opaque and transparent precious stones, and for painting and varnishing real porcelain and earthen and potters ware. This colour is inditpenfably neceffary to the painter when he is defirous of imitating the fine azure colour of many butterflies and other natural objects; and the cheaper kind is employed to give a blueish tinge to new-washed linen, which so readily changes to a dilagreeable yellow, though not without injury to the health as well as to the linen.

Professor Beckmann, in his History of Inventions, gives the following account of the paint prepared from cobalt. "About the end of the 15th century cobalt appears to have been dug up in great quantity in the mines on the borders of Saxony and Hohemia, discovered not long before that period. As it was not known at first to what use it could be applied, it was thrown afide as a useless mineral. The miners had an averhou to it, not only because it gave them much fruitless lahour, but because it often proved prejudicial to their health by the arfenical particles with which it was combined; and it appears even that the mineralogical name cobalt then first took its rife. At any rate, I have never met with it before the beginning of the 16th century; and Mathefius and Agricola fecun to have first used it in their writings. Frisch derives it from the Bohemian word kow, which fignifies metal; but the conjecture that it was formed from cobalus, which was the name of a spirit that, according to the superstitious notions of the times, haunted mines, destroyed the labours of the miners, and often gave them a great deal of unnecessary trouble, is more probable; and there is reafon to think that the latter is borrowed from the Greek. The miners, perhaps, gave this name to the mineral out of joke, because it thwarted them as much as the suppofed fpirit, by exciting falle hopes and rendering their la-bour often fruitless It was once customary, therefore, to introduce into the church-service a prayer that God would preferve miners and their works from kobolts and

" Respecting the invention of making an useful kind of blue glass from cobalt, we have no better information than that which Klotzsch has published from the papers of Christian Lehmann. 'The former, author of an historical work respecting the upper district of the mines. in Misnia, and a clergyman at Scheibenberg, collected

Cobalt. with great diligence every information that respected the history of the neighbouring country, and died at a great age in 1688. According to his account, the colourmills at the time when he wrote were about a hundred years old; and as he began first to write towards the end of the thirty years war, the invention feems to fail about 1540 or 1560. He relates the circumstance as follows: 'Christopher Schurer, a glass-maker at Plat. ten, a place which belongs still to Bohemia, retired to Neudeck, where he established his business. Being once at Schneeberg, he collected some of the beautiful coloured pieces of cobalt which were found there, tried them in his furnace; and finding that they melted, he mixed some cobalt with glass metal, and obtained fine blue glass. At first he prepared it only for the use of the potters; but in the course of time it was carried as an article of merchandise to Nuremberg, and thence to Holland. As painting on glass was then much cultivated in Holland, the artists there knew better how to appreciate this invention. Some Dutchmen therefore repaired to Neudeck, in order that they might learn the process used in preparing this new paint. By great promifes they persuaded the inventor to remove to Magdeburg, where he also made glass from the cobalt of Schneeberg; but he again returned to his former residence, where he constructed a handmill to grind his glass, and afterwards erected one driven by water. At that period the colour was worth 7 dollars per cwt. and in Holland from 50 to 60 florins. Eight colour mills of the same kind, for which roafted cobalt was procured in casks from Schneeberg, were soon constructed in Holland; and it appears that the Dutch must have been much better acquainted with the art of preparing, and particularly with that of grinding it, than the Saxons; for the Elector John George fent for two colour-makers from Holland, and gave a thousand florins towards the enabling them to improve the art. He was induced to make this advance chiefly by a remark of the people of Schneeberg, that the part of the cobalt which dropped down while it was roafting contained more colour than the roafted cobalt itself. In a little time more colour-mills were erected around Schneeberg. Hans Burghard, a merchant and chamberlain of Schneeberg, built one, by which the eleven mills at Platten were much injured. Paul Nordhoff, a Frieslander, a man of great ingenuity, who lived at the Zwittermill, made a great many experiments in order to improve the colour; by which he was reduced to so much poverty that he was at length forced to abandon that place, where he had been employed for ten years in the colour-manufactory. He retired to Annaberg, established there in 1649, by the affistance of a merchant at Leiplic, a colour manufactory, of which he was appointed the director; and by these means rendered the Annaberg cobalt of utility. The confumption of this article, however, must have decreased in the course of time; for in the year 1659, when there were mills of the fame kind at more of the towns in the neighbourhood of mines, he had on hand above 8000 quintals.' Thus far Lehmann."

Kossler fays, that the Bohemian cobalt is not so good as that of Misnia, and that its colour is more like that of ashes. We trust, however, that the qualities of foreign cobalt shall foon be a matter of little importance to the British artist, as a rich mine of this mineral has lately been discovered near Penzance in Cornwal.

COFFEA, the COFFEE-Tree, is a plant which has Coff been botanically described in the Encyclopædia Britan. nica, where some account is likewise given of the modes of cultivating it, as well as of the qualities of its fruit. Since that account, however, was published, two works have fallen into our hands, from which we deem it our duty to make fuch extracts as may not only correct fome mistakes which we had committed, but also communicate useful information to the public.

In our former article we adopted the common opinion, that the coffee produced in Arabia is fo greatly superior to that which is raised everywhere else, that it is vain to think of cultivating the plant to any extent in the West India islands. We are happy to find that this is a vulgar error. In the year 1783, when the cultivation of coffee was not fo well understood in Jamaica as at present, some samples from that island were produced in London, and pronounced by the dealers to be equal to the very best brought from the East. "Two of the famples were equal to the best Mocha coffee, and two more of them superior to any coffee to be had at the grocers shops in Loudon, unless you will pay the price of picked coffee for it, which is two shillings per pound more than for that which they call the best coffee. All the rest of the samples were far from bad coffee, and very little inferior, if at all, to what the grocers call best coffee *."

If this be so, it surely becomes the legislature of Treat Great Britain to encourage the cultivation of coffee in the West Indies, especially as it thrives best in soil which is not fit for the fugar-cane, and may be raifed in confiderable quantities by those who are not able to stock a sugar plantation. The encouraging every article which increases the intercourse with our colonies is increasing our commerce. The payment for all the staples of the West Indies is made in our manufactures; the sale of which must increase in proportion to the numbers that are employed in the cultivation of what is bartered for them. Our West India islands, without draining us of specie or bullion, can supply us with many of those very articles for which we are drained in other parts of the world, and particularly with coffee.

To give a detailed account of the introduction of the coffee tree into the West Indies, would swell this article to very little purpose. According to Boerhaave, a Dutch governor was the first person who procured fresh berries from Mocha, and planted them in Batavia; and in the year 1690 fent a plant from thence to Amsterdam, which came to maturity, and produced those berries which have fince furnished all that is now cultivaten in the Wcst Indies.

In 1714 a plant from the garden of Amsterdam was fent by Mr Pancras, a burgomaster, and director of the botanic garden, as a prefent to Louis XIV. which was placed in the garden at Marly. In 1718 the Dutch began to cultivate coffee in Surinam; in 1721 the French began to cultivate it at Cayenne; in 1727 at Martinico; and in 1728 the English began to cultivate it in Jamaica.

As it has been more cultivated in the French West India islands than in the British, it may be of importance to our colonists' to be made acquainted with the practice of the Freuch planters. Accordingly Dr Laborie, a royalist of St Domingo, has lately published a volume for their instruction on this subject; in which

are many judicious observations, the result of long experience, respecting the soil fit for a coffee-plantation; the various establishments necessary; the cultivation of the coffee-tree through the feveral stages of its growth and duration; and the management and use of the ne-

groes and cattle.

With respect to soil, it is a fact, fays he, beyond contradiction, that low lands, and even the mountains near the champaign country, are less proper for the production of coffee, than lands which are high and at a distance from the sea. The coffee-tree delights in a comparatively cool climate, and in an open and permeable virgin foil; and is hurt by the parching destructive air of the fea. The foil on the mountains of St Domingo confills generally of a bed of mould more or lefs deep; but which, for the production of coffee-trees, ought not to be less than four or five feet. If the declivity be gentle, the foftest and most friable earth is preferable to all others; but in fleep grounds a firm though not clayey foil, mixed with a proportion of gravel or small stones, through which the water may find an eafy way, is the most defirable. The colour of the ground is of little confequence, though fuch as is somewhat reddish is generally to be preferred. With regard to exposure, the north and west are the most eligible in low and hot situations, because these exposures are the coolest; and on the highest mountains the fonth and east are to be chosen, because they are the hottest. On the whole, neither the highest nor the lowest situations are the best, but those which are considerably above the middle of the mountains.

Whatever be the planter's circumstances in point of fortune, and our author thinks that he ought not to undertake a fettlement without the command of 3000 or 4000 pounds flerling, he ought not to fet out with a great number of negroes. If he cannot command a plentiful fupply of victuals from fome contiguous plantation, fix, or at the most twelve, male negroes, with one or two women, will be found fufficient to make the first essay. After building two huts, one for the master or overfeer and the other for the flaves, they are to commence their operations by cutting away the underwood and creeping plants with the bill, and felling the trees The trees are to be cut as low as possible, but the roots are to be left in the ground, because they preserve the foil during the first period of culture; and in burning this mass of wood and shrubs, the only way sometimes of clearing the ground, care must be taken that the fire be nowhere so violent as to convert the soil into the confishence of brick, which it is very apt to do if the soil be clayey. Amid the coffee-trees, after they are planted, may be fown beans, maize, and all kinds of efculent plants, pot herbs, and roots; but particular care must be taken to remove from these plantations all creeping plants, fuch as melons, yams, potatoes, gourds, and more especially tobacco, which multiplies to a vast extent, and exhaufts the ground.

In St Domingo the most approved method of planting the coffee-tree is in fliaight rows croffing each other at right angles, and the distance between the plants is regulated by the quality and exposure of the ground. The richer the foil, the exposures being the fame, and the cooler the exposure, the quality of the foil being the same, the farther must the trees be planted afunder. If on the north and west the ground be good, plant still

SUPPL. VOL. I. Part II.

farther; but, on the contrary, if to the east or fouth it Coffea. be light (which it generally is), plant still nearer. Thus if it be proper on a fouth or east exposure to plant at the distance of six feet, it will be necessary to plant at the diffance of feven on a west or north exposure, if the ground be of the fame quality as in the other fituations.

Though coffee, like all other vegetables, grows from the feed, Dr Laborie advises, in the forming of large plantations, to make use of faplings reared in nurse. ries; and the fituation fittest for a nursery is a plain, or at least a ground of gentle afcent, where the mould is crumbly. In forming a nurfery, some plant the whole cherry; but our author recommends the taking off the fkin, and washing the teparated feeds; in which we suspect that he is mistaken, as his practice is certainly a devia-tion from nature. The nursery must be kept very clear of weeds, and neither corn nor any thing elfe fown

The best season for transplanting the saplings is during the genial rains of April and May, when great attention is required, as the treasures of future harvests are at stake. Those plants are the fittest for being removed which, in the language of our author, are crowned, or have each four little boughs; and, if the feeds were fresh and fown in furrows about an inch from each other, this perfection is generally attained in the course of a year. 'The faplings must not be pulled up by force, but carefully railed by means of a flat, sharp, iron shovel, thrust deep under their roots; and the sooner they are planted, after being taken up, the better.

In planting, the first thing to be done is to thrust into the ground a dibble, or sharp pointed stick, round which a hole is dug from nine to twelve inches in diameter, and from fifteen to eighteen in depth. Then a quantity of the mould taken out of the hole is thrown back into it, till its depth be diminished about four or six inches; and the plant being supported with the left hand, in the middle of the hole, while the end of its straight root, which our author calls its pivot, touches lightly the new bed, the furrounding mould is with the right hand thrown in, to the height of fix inches. This being lightly pressed down with both hands, more earth is thrown in and preffed in the fame manner, care being taken not to hurt, or bend, or displace the fapling, which must be set so deep that its two inferior branches be rather below the level of the ground. On this account three or four inches of the hole are left open, which, by the time that these branches rise above its margin, are filled up by the furrounding earth. The butiness is finished by finking the sharp-pointed stick at the upper margin of the hole, where it ferves as a small fence to the infant tree. In hot fituations plantain trees are intermingled with the coffee trees for the purpose of shade and coolness. They are usually placed in every fourth or fixth row, as the trees are more or less distant, and the exposure more or less hot.

To the business of planting very soon succeeds that of weeding; for there is hardly any plant to which weeds are fo pernicious as the coffee tree: they cause it to grow yellow, fade, wither, and perish. Where the ground flopes much, especially if the soil be foft and friable, the weeds must be taken up by the hand; for if they be rooted out by the hoe, the foil will be fo loofened that the rains will fweep it away. Some

. 3 K

Coffea. weeds, however, from the depth of their roots must be dug up; and when that is the case the earth must be carefully returned and pressed down. If, in weeding, any faplings be found withered, others of the fame fize must be brought from the nursery and planted in their flead, with what our author calls their clod, i. e. with the earth of the nursery adhering to their roots. If any fapling be found broken or twifted, it must be cut close by the ground in a floping direction, the cut furface facing the north, and it will foon put forth fuckers, of which the best only need be preserved. In plantations of eighteen or twenty-months old trees are often found with yellow, withered leaves, of which the cause is fometimes a premature load of fruit, which must therefore be instantly removed or the tree will perish. If, after this, it begin not in a few days to recover, it is probably eaten at the roots by a large white worm refembling a flug. In that case the tree must be removed, the worm taken out, and before another tree be planted in its flead, a large hole must be made in the ground, exposed to the influence of the fun at least for a fortnight.

The natural height of the coffee tree is from 15 to 18 feet; and if left to itself it would have the form of most other trees, i. e. a naked trunk and a branchy head. This is prevented by what the planters call stopping; which is performed by cutting off the top of the tree when it has arrived at the proper height, which varies according to circumstances. In the best soil and most genial exposure, it is suffered to grow to the height of five feet, and in the worst stopped at two; but under the fame aspect, and on ground of the same quality, all the trees ought to be stopped at the same height. This operation of stopping is very apt to make the trees put forth fuperfluous branches, which renders them inacceffible to the genial warmth of the sun, and, of course, deficient in the powers of fructification. These must be plucked away while yet tender; for if they be suffered to grow till it become necessary to cut them, a number of sprouts succeed; whereas, when they are plucked, the wound foon cicatrizes, and nothing follows.

The faw and the knife, however, must sometimes be used; for when trees grow old their heads are apt to spoil; superfluous branches may have been left upon them through neglect; a bough may have been broken by accident; or branches may be spent by too great a load of fruit. In all these cases recourse must be had to pruning, which should be performed immediately after crop, and in fuch a manner as that the tree, when it puts forth its new branches, may still have as much as possible its natural or former appearance. This will be accomplified by cutting the withered bough immediately above a knot, whence a good fecondary branch is put forth, which may be eafily trained into the proper shape. Our author directs the cut to be always made fo as that the sloping surface shall face the north; by which exposure it will escape the injury which it would otherwise receive from the excessive heat of the fun. This is a good advice; but it would still be an improvement on it to treat the wound with Forfyth's or Hit's plaster, which we have described elsewhere (See Encycl. Vol. XVIII. page 562). When the tree is completely pruned, the moss and other excrescences must be scraped from the trunk with a wooden knife, great care being taken not to injure the bark.

After pruning follows what is called nipping. This Co is nothing more than the removal of those superfluous fmall twigs which are fent forth from every cut furface in fuch numbers as would foon exhaust the tree; and it is called nipping, because they are plucked away by the hand, and not cut by the knife. It is needless to add. that when the ground begins to be impoverished, it must be enriched by proper manure. This is known to every husbandman both in Europe and in the West Indies; but it is not perhaps fo generally known that the weedings, and chiefly the red skins of coffee, when gathered into pits, are, in process of time, converted into a black mould, which our author fays makes the very best manure.

"The fruit of the coffee, when perfectly ripe, appears like a small oval cherry. Under a red and shining skin a whitish clammy luscious pulp presents itself, which generally incloses two seeds. These seeds have one side flat, the other hemispherical. The first is marked with a longitudinal fiffure, and the flat fides are applied to each other. When the feeds are opened, they are found covered with a white, ligneous, brittle membrane, denominated parchment; on the infide of which is another filver-coloured membrane, exceedingly thin, and feeming to originate from the fiffure of the feeds. Sometimes the cherry has but one feed or grain, which then is in the form of a small egg. This is peculiar to old decayed trees, or to the extremities of some

fmall branches." The business of preparation consists in taking the feed from its covering, in drying, and in cleaning it fo as to have every advantage at market. Our author thinks that the best method of preparing the coffee is to strip the seed of its outer skin immediately on its being pulled, and to dry it in its parchment. The procels has been already described in the Encyclopædia; but we believe it to be an injudicious one. We have the authority of a very eminent botanist *, well ac *, n quainted with all the vegetable productions of the Welt with Indies, to fay, that the improvement which we have there mentioned, as proposed by Mr Miller, is greatly preferable to Dr Laborie's practice. Indeed he himfelf admits, that coffee dried in the cherry is more heavy than when dried in parchment, and that it generally has a higher flavour. Nay, he fays expressly, that " if a planter wants to have coffee of the first quality, either for himself or for his friends, he must set a part a number of his oldest trees, and not gather the fruit till it is ripened into dryness. It is in that manner, he believes, that the Arabians in Yemen make their little harvests; and he declares, that coffee thus nourished on the tree to the last moment, must have every perfection of which it is capable." His only plaufible objection is, that the trees are foon exhaufted when the fruit is left fo long upon them; but doubtless this exhaustion might be retarded by proper manure.

The chemical analysis of coffee evinces that it posfesses a great portion of mildly bitter and lightly astringent gummous and refinous extract; a confiderable quantity of oil; a fixed falt; and a volatile falt .- Thele are its medicinal constituent principles. The intention of torrefaction is not only to make it deliver those principles, and make them foluble in water, but to give it a property it does not possess in the natural state of the berry. By the action of fire, its leguminous tafte and

the aqueous part of its mucilage are destroyed; its saline properties are created and difengaged, and its oil is rendered empyreumatic. - From thence arises the pungent fmell, and exhilarating flavour, not found in its natural state.

The roafting of the berry to a proper degree requires great nicety: Du Four justly remarks, that the virtue and agreeableness of the drink depend on it, and that both are often injured in the ordinary method. Bernier fays, when he was at Cairo, where it is fo much used, he was affured by the best judges, that there were only two people in that great city, in the public way, who understood the preparing it in perfection. If it be under-done, its virtues will not be imparted, and in use it will load and oppress the stomach: - It it be overdone, it will yield a flat, burnt, and bitter taste, its virtues will be destroyed, and in use it will heat the body,

and act as an aftringent.

Fourteen pounds weight of raw coffee is generally reduced, at the public roasting houses in London, to eleven pounds by the roasting; for which the dealer pays feven pence half penny, at the rate of five shillings for every hundred weight. In Paris, the same quantity is reduced to ten pounds and an half. But the roafting ought to be regulated by the age and quality of the coffee, and by nicer rules than the appearance of the fumes, and fuch as are usually practited: therefore the reduction must consequently vary, and no exact standard can be ascertained. Besides, by mixing different forts of coffee together, that require different degrees of heat and roafting, coffee has feldom all the advantages it is capable of receiving to make it delicate, grateful, and pleasant. This indeed can be effected no way so well as by people who have it roafted in their own houses, to their own taste, and fresh as they want it for use. The closer it is confined at the time of roafting, and till used, the better will its volatile pungency, flavour, and virtues, be preserved.

The mode of preparing this beverage for common use differs in different countries, principally as to the additions made to it -But though that is generally understood, and that taste, constitution, the quality of the coffee, and the quantity intended to be drunk, must be confulted, in regard to the proportion of coffee to the water in making it - yet there is one material point, the importance of which is not well understood, and

which admits of no deviation.

The preservation of the virtues of coffee, particularly when it is of a fine quality, and exempt from rankness, as has been faid, depends on carefully confining it after it has been roasted; and not powdering it until the time of using it, that the volatile and æthereal principles, generated by the fire, may not escape. But all this will fignify nothing, and the best materials will be useless, unless the following important admonition is ftrictly attended to; which is, that after the liquor is made,-it should be bright and clear, and entirely exempt from the least cloudiness or foul appearance, from a suspension of any of the particles of the substance of the coffee.

There is scarcely any vegetable infusion or decoction Coffer, whose effects differ from its gross origin more than that Colchester. of which we are speaking. Coffee taken in substance causes oppression at the stomach, heat, nausea, and indigestion: consequently a continued use of a preparation of it, in which any quantity of its substance is contained, besides being disgusting to the palate, must tend to produce the same indispositions. The residuum of the roafted berry, after its virtues are extracted from it. is little more than an earthy calx, and must therefore be

The want of attention to this circumstance has been the cause of many of the complaints against coffee, and of the aversion which some people have to it; and it is from this confideration that coffee should not be prepared with milk instead of water, nor should the milk be added to it on the fire, as is fometimes the case, for economical dietetic purposes, where only a small quantity of coffee is used, as the tenacity of the milk impedes the precipitation of the grounds, which is necesfary for the purity of the liquor, and therefore neither the milk nor the fugar should be added until after it is made with water in the usual way, and the clarification of it is completed (A). - The milk should be hot when added to the liquor of the coffee, which should also be hot, or both should be heated together, in this mode of using coffee as an article of sustenance.

If a knowledge of the principles of coffee, founded on examination and various experiments, added to obfervations made on the extensive and indiscriminate use of it, cannot authorife us to attribute to it any particular quality unfriendly to the human frame; -if the unerring test of experience has confirmed its utility, in many countries, not exclusively productive of those inconveniences, habits, and diseases, for which its peculiar properties feem most applicable-let those properties be duly confidered; and let us reflect on the flate of our atmosphere, the food and modes of life of the inhabitants, - and the chronical infirmities which derive their origin from these sources, and it will be evident what falutary effects might be expected from the general

dietetic use of coffee in Great Britain.

COFFER-Dams, or Batardeaux, in bridge-building, are inclosures formed for laying the foundation of piers, and for other works in water, to exclude the furrounding water, and so prevent it from interrupting the work.

COLCHESTER, the chief town in Effex, is described in the Encyclopædia Britannica; but the defcription is in many respects erroneous. The following account of it was fent to us by an obliging correspondent, who is defirous that the place of his nativity may

be accurately described in this Supplement.

Colchester is pleasantly situated upon an eminence, gradually rifing on the fouth fide of the river Colne. It is the ancient Colonia Camulodunum, from which word Colonia, both the town and the river Colne, received their names. The Saxons called it Colneceaster. That it flourished under the Romans, feveral buildings full of their bricks, and innumerable quantities of coin

(A) It is not to coffee alone that this reflection is confined; every article we use as a diluter demands the same attention. Malt liquors, particularly small beer, which in this respect is much neglected, ought always to be carefully fined. The faculent matter entangled by the mucilage of the malt is hurtful to digeflion, and detrimental to health.

Colchester, dug up in and about it, fully evince. In the year 1763, Colours a curious teffellated or mosaic pavement was found in the garden of the late Mr Barnard, surgeon in the High Street, now the property of Mr John Wallis, about three feet under the surface of the earth. The emperor Constantine the Great was born here, his mother Helen being daughter of Cool, governor or king of this district under the Romans. She is faid to have found out the cross of Christ at Jerusalem; and on that account the arms of this town are a cross regulee between three ducal coronets, two in chief and one in base, the coronet in base passing through the cross.

The walls wherewith the town was encompassed are still tolerably entire on the fouth, east, and west sides, but much decayed on the north fide: they are generally about nine feet thick. By a statute of King Henry VIII. this town was made the see of a suffragan bishop.

This town is the most noted in England for making of baize; is is also of special note for candying the erin-

go roots, and for oysters.

In the conclusion of the civil war 1648, this town suffered a severe siege of ten weeks; and the besieged making a very resolute defence, the siege was turned into a blockade, wherein the garrison and inhabitants fuffered the utmost extremity of hunger, being reduced to eat horse-flesh, dogs, and cats, and were at last obliged to furrender at discretion, when their two valiant chief officers, Sir Charles Lucas and Sir George Lifle, were shot under the castle walls in cold blood. Colchester is a borough by prescription, and under that right fends two members to parliament, all their charters being filent upon that head. The charter was renewed in 1763. The town is now governed by a mayor, recorder, 12 aldermen, 18 affiftants, and 18 common-council men. Quarter sessions are held here four times in the year.

The famous abbey gate of St John is still standing, and allowed to be a furprifing, curious, and beautiful piece of Gothic architecture, great numbers of perfons coming from remote parts to fee it. It was built, together with the abbey, in 1097, and Gudo, steward to

King William Rufus, laid the first stone.

St Ann's chapel, standing at the east end of the town, is valuable in the esteem of antiquarians as a building of great note in the early days of Christianity, and made no small figure in history many centuries past.

It is now pretty entire.

St Botoph's priory was founded by Ernulphus in the reign of Henry I. in the year 1110. It was demolished in the wars of Charles I. by the parliament army under Sir Thomas Fairfax. The ruins still exhibit a beautiful sketch of ancient masonry, much admired by the lovers of antiquities. The castle is still pretty entire, and is a magnificent structure, in which great improvements have of late been made. Here is an excellent and valuable library.

The markets, which are on Wednesday and Saturday, are very well supplied with all kind of provisions. There are no less than fix diffenting meeting houses in this town. Colchester is 51 miles from London. It had 16 parish churches, in and out of the walls, but now only 12 are used, the rest being damaged at the

fiege in 1648.

See PIGMENTS in this Supplement. COLOURS. Accidental Colours, a name given to a very curious optical phenomenon, which was first, we believe, at Cole tended to by Buffon. That philosopher wrote a short paper on it, which was published in the Memoirs of the Academy of Sciences for the year 1743.

If a person look stedfastly and for a considerable time at a small red square painted upon white paper, he will at last observe a kind of green-coloured border surround the red square. If he now turn his eyes to some other part of the paper, he will fee an imaginary square of a delicate green bordering on blue, and corresponding exactly in point of fize with the red square. This imaginary square continues visible for some time, and indeed does not disappear till the eye has viewed successively a number of new objects. It is to this imaginary square that the improper name of accidental colour has been given. If the small square be yellow, the imaginary square or accidental colour is blue: the accidental colour of green is red; of blue, yellow; of white, black;

The first person, as far as we know, who gave a satisfactory explanation of these phenomena was Professor Scherffer of Vienna, whose differtation, trauslated by Mr Bernouilli, has been published in the 26th volume of

and on the contrary, that of black is white.

the Journal de Physique.

In order to understand these phenomena, let us recollect, in the first place, that light confists of seven rays, namely, red, orange, yellow, green, blue, indigo, violet; that whiteness consists in a mixture of all these rays; and that those bodies which reflect but very little light are black. Those bodies that are of any particular colour, reflect a much greater quantity of the rays which constitute that particular colour than of any other rays. Thus red bodies reflect most red rays; green bodies, most green rays, and so on.

Let us recollect, in the fecond place, that when two impressions are made at the same time upon any of our organs of sensation, one of which is strong and the other weak, we only perceive the former. Thus if we examine by the prism the rays reflected by a red rose, we shall find that they are of four kinds, namely, red, yellow, green, and blue. In this case, the impression made by the red rays makes that made by the others quite insensible. For the same reason, when a person goes from broad day light into an ill-lighted room, it appears to him at first perfectly dark, the preceding ftrong impression rendering him for some time incapable

of feeling the weaker impression.

With the affiftance of these two remarks, it will not be difficult to explain the phenomena of accidental colours. When a person considers attentively for some time a white square lying on any black substance (paper for inflance), it is evident that the part of the retina on which the white square is painted, receives a stronger impression than any other part; at least the greatest number of rays strike upon it. A weaker impression, therefore, will act on it with much less force than upon the rest of the retina. Consequently, when the eye is turned from the white square to some other part of the black paper, a square is perceived of the same size with the white square, and much blacker that any other part of the paper; this is evidently in consequence of the weaker impression made by the rays reslected by the black paper upon that part of the eye previously fatigued by the copious reflection from the white square. For the very same reason, if, after looking for a suffiColours. cient time at a white square lying on a black ground, we turn our eyes upon a sheet of white paper, we perceive a very well defined black fquare. In this cale, the part of the retina already fatigued is not fo fenfible to the rays reflected by the white paper as the other parts of it which have not been fatigued. 'I'he reason then that black is the accidental colour of white is sufficiently evident.

On the contrary, when we look a sufficient time at a Llack square lying upon a white ground, if we turn our eyes to any other part of the white paper, or even upon black paper, we shall perceive a small square answering to the black square, and much brighter than any other part of the paper: evidently because that part of the retina on which the black square was painted being less fatigued is more susceptible of impressions than any other part of the eye. Thus we fee why the accidental colour of black is white, and why that of white on the contrary is black. These facts, indeed, have been long known, and they have been generally explained in this

When a person has looked for a sufficient time at a red square placed on a sheet of white paper, and then turns his eyes to another part of the paper, that part of the retina on which the red was painted being fatigued, the red rays reflected from the white paper cease to make any fenfible impression on it, and consequently there will be feen upon the white paper a square similar to the red square, and the colour of which is that which would refult from the mixture of all the rays of light except the red. In general, therefore, the accidental colour is the colour which results from the mixture of all the rays of light, those rays excepted which are the same with the primitive colour.

Now, in order to discover these accidental colours, let us recollect the manner which Newton employed to determine the colour which refults from the mixture of leveral others, the species and quantity of which are known. He did it by dividing the circumference of a circle, so that the arches are to one another in the proportion of a string shortened by degrees, in order to found one after another the notes of an octave; which is nearly the proportion that the different rays occupy when light is decomposed by means of the prism. Or suppose the circumference of the circle, as usual, divided into 360 degrees, the different rays, according to Benvenut, should occupy the following arches:

Orange, 27 .. Yellow, 48. Green, 60. Blue, Indigo, -

Let us now compare the action of colours on one another with that of different weights; and for that purpose let us suppose each colour concentrated in the centre of gravity of its arch. In order to find the colour resulting from any mixture, we have only to find the common centre of gravity of the arches which represent the different colours: The colour resulting from the mixture will be that of the arch to which the common centre of gravity approaches nearest. And if that common centre of gravity is not in the straight line which joins the centre of the circle, and the centre of gravity

of the arch to which it is most contiguous, the result- Colours. ing colour will approach more or less to the colour of the contiguous arch towards which the line, paffing through the centre of the circle, and the common centre of gravity of the arches, falls. And farther, the refulting colour will be more or lefs deep according to the distance of the common centre of gravity from the centre of the circle.

In the case under consideration at present, namely, to determine the different accidental colours, the application of this method is remarkably eafy; because only one of the feven primitive colours is excluded, and confequently the fix colours from the mixture of which we wish to know the refulting colour are all contiguous. For it is evident, that the fum of the fix arches, representing thefe fix colours, will be divided into two equal parts by the line which passes through the centre of the circle and their common centre of gravity; and that if the same line be produced till it reaches the circumference of the circle on the other fide, it will also divide the arch reprefenting the feventh or omitted colour into two equal parts. Let us suppose, for instance, that the violet is omitted, and that we wanted to know the colour resulting from the mixture of the other fix colours, we have only to bifect the arch representing the violet, and from the point of lection to draw a diameter to the circle, the arch of the circle opposite to the violet through which the diameter passes will indicate the colour of the mixture. The arch representing the violet being 80°, let us take. the half of it, which is 40°, and let us add to it 45° for the red, 27° for the orange, and 48° for the yellow, we shall have 160°, which wants 20° of half the circumference of the circle. If now we add the 60° for the green, the fum total will be 220°, confiderably more than half the circumference; consequently the common centre of gravity is nearest the green arch; but it falls 100 nearer the yellow than the straight line which joins the centre of the circle and the centre of gravity of the green arch. Hence we fee that the resulting colour will be green, but that it will have a shade of yellow.

It is evident, then, that the accidental colour of violet must be green with a shade of yellow; and this is actually the case, as any one may convince himself by

making the experiment.

Suppose, now, we wanted to know the accidental colour of green, or, which is the fame thing, the colour refulting from the mixture of all the primitive rays except the green. The green arch is 60°, the half of which is 30°; if to this we add 60° for the blue arch, and 40° for the indigo arch, we shall have 130°, or 50° degrees less than a semicircle. If to this we add the violet arch, which is 800, we shall have 30" more than the semicircle; consequently the common centre of gravity falls nearest the violet, and it is 100 nearer the red arch than is the centre of gravity of the violet arch. Hence we know that the accidental colour of green will be violet or purple, with a shade of red: And experiment confirms this.

Buffon observed, that the accidental colour of blue was reddish and pale. Let us see whether we shall obtain the same result from our method. Let us suppose that Buffon employed a light blue. In that case, it to 30, the half of the blue arch, we add 60 for the green, 48 for the yellow, and 27 for the orange, we shall have 165°, or 15° less than half the circumference of the

circle:

Colours. circle: Confequently the common centre will fall nearest the red ach, but within 15° of the orange The accidental colour must therefore be red, with a shade of orange; or, which is the same thing, it must be a pale red.

In the same manner we may discover, that the accidental colour of indigo is yellow, inclining a good deal to orange; and that the accidental colour of indigo and blue together is orange, with a strong shade of red. Both of which correspond accurately with experiment.

It would be easy to indicate, in the fame manner, the accidental colour of any primitive colour, if what has been faid were not fufficient to explain the cause of accidental colours, and to show that their phenomena correspond exactly, both with the Newtonian theory of optics, and with what we know to be laws of our fenfations in other particulars.

From the theory above given, which is that of Professor Scherffer, the following confequences may be deduced:

1. The accidental colour of a red square, lying upon a white or a black ground, ought to be blackish, if we cast our eyes upon a red coloured surface. 2. If the furface upon which we look at a red fquare be itself coloured, if it be yellow, for instance, the white paper upon which we afterwards cast our eyes will appear blue, with a green square in it corresponding to the original red square. And, in general, we ought to perceive the accidental colour of the ground on which the square is placed, as well as the square itself. 3. If while we are looking at the little square we change the situation of the eye, fo that its image shall occupy a different place on the retina, when we turn our eyes to the white paper we shall fee two squares, or at least one unlike the figure of the original one. 4. If the white paper on which we look be farther diffant than the little fquare was, the imaginary fquare will appear confiderably larger than the true one. 5. If while we are looking at the little square, we gradually make the eye approach to it, without altering its fituation, the imaginary square will appear with a pale border. These, and many other confequences that might eafily be deduced, will be found to take place conftantly and accurately, if any one chooses to put them to the test of experiment; and therefore may be confidered as a complcte confirmation of the theory given above of the cause of accidental colours.

There is another circumstance respecting accidental colours which deserves attention. If we continue looking stedfastly at the little square longer than is necessary, in order to perceive its accidental colour, we shall at last see its border tinged with the accidental colour of the ground on which the fquare is lying. For inflance, if a white square be placed upon blue paper, its border becomes yellow; if upon red paper, it becomes green; and it becomes reddish upon green. In like manner, the border of a yellow fquare becomes greenish upon a red ground, and that of a red square on a green ground becomes purple.

The cause of this phenomenon seems to depend upon the contraction and extension of the image of the square painted on the retina. We know for certain, that the diameter of the pupil changes during our inspecting the fquare; at first it becomes less, and afterwards increases. And though we cannot fee what passes in the bottom of the eye, we can fearcely doubt that fimilar move-

ments are going on there, if we attend to the changes

that are continually taking place in the border of our Colo little square; sometimes it is large, sometimes small; at one time it disappears altogether, and the next moment Con makes its appearance again.

There is another phenomenon connected with accidental colours, which it is not fo easy to explain; name. ly, that if we look at these little squares for a very long time, till the eye is very much fatigued, their accidental colours will appear even after we shut our eyes. The very fame thing takes place if we attempt to look at a very luminous object; as the fun, for inflance. Professor Scherffer thinks that this may be partly owing to the light which still passes through the eye-lids. That fome light-passes through the eye lids is evident, because when we look towards a strong light with our eye lids thut, we fee diftinctly their colour, derived from the blood veffels with which they are filled; and if we pass our finger before our cyes, we fee the shadow of the finger though our eye-lids be shut, provided our eyes be turned towards the window. But that this light is not fufficient to explain the phenomenon in question is evident from this circumstance, that the same accidental colours make their appearance though we go immediately into the darkest place. Perhaps we have accounted for the phenomenon elsewhere (See META-PHYSICS, Encycl. no 54.). We pass over the other conjectures of Profesfor Schersfer, which are exceedingly ingenious, but not fufficiently supported by facts to be

COLUMBA NOACHI, Noah's dove, a small constellation in the fouthern hemisphere, confifting of 10 stars.

COMAR, or KHOMAR, a Zemindar's demesne of

COMBUSTION. See CHEMISTRY in this Sup-

plement, nº 293.

COMPASS, or Mariner's Steering Compass, is an instrument of so great value, that every improvement of it, proposed by men of science or of experience, is intitled to notice. We shall therefore lay before our readers fome observations on the defects of the compass in common use, which have fallen into our hands fince the article in the Encyclopædia was published. first is by Captain O'Brien Drury of the royal Navy, and relates entirely to the needle.

" Experience (fays this officer) shews us, that the needle of a compais, as well as all other magnets, whether artificial or real, perpetually lofes fomething of its magnetic powers, which often produces a difference exceeding a point; and I am well convinced that the great errors in ship-reckonings proceed more frequently from the incorrectness of the compais than from any

"Steel cannot be too highly tempered for the needle of a sea-compass, as the more it is hardened the more permanent is the magnetism it receives; but, to preferve the magnetism, and consequently the polarity of the needle, I recommend to have the needle cased with thin, well-polished, soft iron; or else to have it armed at the poles with a bit of foft iron. I have found, from many experiments, that the cased needle preserved its magnetism in a much more perfect degree than the needle not cased; and I have sometimes thought that the magnetic power of the cased needle had increased, while the magnetic power of the uncased and unarmed needle always lofes of its polarity."

This is not an opinion taken up at random, but is the refult of what appears to have been a fair and judicious experiment; for our author placed a cased needle, an armed needle, and one wi hout either case or armour, in a room for three months; each having at that time precisely the same direction, and nearly the same degree of force. At the expiration of the three months, he found that the cased needle and the armed needle had not in the least changed their direction; but the other had changed two degrees, and had lost very considerable of its magnetic power. If there was any change in either of the other needles, it was too inconsiderable to be perceived.

These observations seem to be new, and may tend to the improvement of the compass. But it is not with respect to the needle only that this instrument is desective. Mr Bernard Romans of Pensacola well observes, that, on another account, the heaviest brass compasses now in use are by no means to be relied on in a hollow or high sea. This is owing to the box hanging in two brass rings, confining it to only two motions, both vertical and at right angles with each other; by which confinement of the box, upon any succussion, more especially sudden ones, the card is always put into too much agitation, and, before it can well recover itself, another jerk prevents its pointing to the pole; nor is it an extraordinary thing to see the card unshipped by the violence of the ship's pitching.

All these inconveniences are remedied to the full by giving the box a vertical motion at every degree and minute of the circle, and compounding these motions with a horizontal one of the box as well as of the card. By this unconfined disposition of the box, the effects of the jerks on the card are avoided, and it will always very steadily point to the pole. "Experience (says our author) has taught me, that the card not only is not in the smallest degree affected by the hollow sea, but that, in all the violent shocks and whirlings the box can receive, the card lies as still as it in a room unaffect-

ed by the least motion.

"Lately a compass was invented and made in Holland, which has all these motions. It is of the fize of the common brass compasses; the bottom of the brass box, instead of being like a bowl, must be raised into a hollow cone, like the bottom of a common glass bottle; the vertex of the cone must be raised so high as to leave but one inch between the card and the glass; the box must be of the ordinary depth, and a quantity of lead must be poured in the bottom of the box, round the base of the cone; this secures it on the stile whereon

it traverses.

"This stile is firmly fixed in the centre of a square wooden box, like the common compass, except that it requires a thicker bottom. The stile must be of brass, about six inches long, round, and of the thickness of one-third of an inch; its head blunt, like the head of a sewing-thimble, but of a good polish: the stile must stand perpendicular. The inner vertex of the cone must also be well polished; the vertical part of the cone ought to be thick enough to allow of a well-polished cavity, sufficient to admit a short stile, proceeding from the centre of the card whereon it traverses. The compass I saw was so constructed; but I see no reason why the stile might not proceed from the centre of the vertex of the cone, and so be received by the eard the

common way. The needle must be a magnetic bar, Compassiblunt at each end; the glass and cover are put on in the common way."

A compass of this kind was submitted to our author's examination by the captain of a sloop of war, who assured him, that in a hard gale, which lasted some days, there was no other compass of the smallest service. Mr Romans was satisfied that the officer did not praise the apparatus more than it deserved; and we feel ourselves strongly inclined to be of the same opinion.

It must not be concealed, however, that the ingenious Mr Nicholfon feems to think very differently of all fuch contrivances. In a paper published in the ninth number of his valuable Journal, he labours to prove, that the compass is very little disturbed by tilting the box on one fide, but very much by fudden horizontal changes of place; that a scientific provision against the latter is therefore the chief requifite in a well made inftrument of this kind; and that no other provision is requifite, or can eafily be obtained, than good workmanship according to the common construction, and a proper adjustment of the weight with regard to the centres or axes of suspension. The same author is of opinion, that it would greatly improve the compass to make the needle flat and thin, and to suspend it, not, as is most commonly done, with its slat side, but with its edge uppermost; for it being a well-known sact, that soft steel loses its magnetism sooner than hard, it is obvious, that unless both sides of a needle be equally hard (which is almost impossible if they be distant from each other), the magnetic power will, in process of time, deviate towards the harder fide.

The Chinese Compass has some advantages over the

European compass, from which it differs with respect to the length of the needle, and the manner in which it is suspended. In the compass of China, the magnetie needle is feldom above an inch in length, and is lefs than a line in thickness. It is poised with great nicety, and is remarkably fensible, or, in other words, points fleadily towards the same portion of the heavens. This fleadiness is accomplished by the following contrivance: " A piece of thin copper is Arapped round the centre of the needle. This copper is rivetted by its edges to the upper part of a small hemispherical cup, of the same metal, turned downwards. The cup fo inverted ferves as a focket to receive a steel pivot rising from a cavity made into a round piece of light wood or cork, which thus forms the compais box. The furfaces of the focket and pivot, intended to neet each other, are perfeetly polished, to avoid, as much as possible, all friction. The cup has a proportionably broad margin, which, befide adding to its weight, tends, from its horizontal position, to keep the centre of gravity, in all situations of the compais, nearly in coincidence with the centre of fulpenfion. The cavity, in which the needle is thus fuspended, is in form circular, and is little more than fufficient to remove the needle, cup, and pivot. Over this cavity is placed a thin piece of transparent tale. which prevents the needle from being affected by any motion of the external air; but permits the apparent motion of the former to be eafily observed. The small and short needle of the Chinese has a material advantage over those of the usual fize in Europe, with regard to the inclination or dip towards the horizon; which, in the latter, requires that one extremity of the needle

should

, ment Conception.

Comple. should be made so much heavier than the other as will counteract the magnetic attraction. This being different in different parts of the world, the needle can only be accurately true at the place for which it had been constructed. But in short and light needles, suspended after the Chinese manner, the weight below the point of fuspension is more than sufficient to overcome the magnetic power of the dip or inclination in all fituations of the globe; and therefore such needles will never deviate from their horizontal position."

COMPLEMENT, in general, is what is wanting, or necessary, to complete some certain quantity or thing.

Arithmetical COMPLEMENT, is what a number or logarithm wants of unity or I with fome number of cyphers. It is best found by beginning at the left-hand fide, and fubtracting every figure from o, except the laft, or right hand figure, which must be subtracted from 10. So, the arithmetical comp. of the log. 9:5329714, by fubtracting from 9's, &c, is 0.4670286.

The arithmetical complements are much used in operations by logarithms, to change fubtractions into additions, which are more conveniently performed, especially when there are more than one of them in the ope-

COMPLEMENT, in astronomy, is used for the distance of a star from the zenith; or the arc contained between the zenith and the place of a star which is above the horizon. It is the same as the complement of the altitude, or co-altitude, or the zenith distance.

COMPLEMENT of the Course, in navigation, is the quantity which the course wants of 900, or 8 points,

viz. a quarter of the compais.

COMPLEMENT of the Curtain, in fortification, is that part of the anterior fide of the curtain which makes the

COMPLEMENT of the Line of Defence, is the remainder of that line, after the angle of the flank is taken away.

COMPLEMENTS of a Parallelogram, or in a Parallelogram, are the two leffer parallelograms, made by drawing two right lines parallel to each fide of the given parallelogram, through the same point in the diagonal.

COMPLEMENT of Life, a term much used, in the doctrine of life annuities, by De Moivre; and, according to him, it denotes the number of years which a given life wants of 86, this being the age which he confidered as the utmost probable extent of life. So 56 is the complement of 30, and 30 is the complement of 56.

COMPOSITION OF PROPORTION, according to the 15th definition of the 5th book of Euclid's Elements, is when, of four proportionals, the sum of the 1st and 2d is to the 2d, as the fum of the 3d and 4th is to the

4th.

Composition of Ratios, is the adding of ratios together: which is performed by multiplying together their corresponding terms, viz. the antecedents together, and the confequents together, for the antecedent and confequent of the compound ratio; like as the addition of logarithms is the fame thing as the multiplication of their corresponding numbers. Or, if the terms of the ratios be placed fraction-wife, then the addition or composition of the ratios is performed by multiplying the fractions together.

COMPOUND INTEREST. See ALGEBRA, Encycl.

and Compound INTEREST in this Supplement.

CONCEPTION, a city of Chili in South America,

was vilited in 1786 by the celebrated, though unfortu. Con nate, navigator La l'erouse, who gives an account of fome particulars relating to it very different from what we have given of it under the article Conception, Encycl. So far are the Spaniards from living in fecurity with respect to the Indians, that, according to him, they are under continual alarms of being attacked by those bold and enterprising favages. "The Indians of Chili (fays he) are no longer those Americans who were inspired with terror by European arms. The increase of horses, which are dispersed through the interior of the immense deferts of America, and that of oxen and sheep, which has also been very great, have converted these people into a nation of Arabs, in every thing refembling those who inhabit the deferts of Ara-Constantly on horseback, they consider an excurfron of two hundred leagues as a very fhort journey, 'I'hey march accompanied by their flocks; feed upon their flesh and milk, and sometimes upon their blood; and cover themselves with their skins, of which they make helmits, cuiraffes, and bucklers. All their old customs are laid aside. They no longer feed upon the fame fruits, nor wear the same dress; but have a more firiking refemblance to the Tartars, or to the inhabitants of the banks of the Red Sea, than to their anceltors, who lived two centuries ago. So decifive an influence has the introduction of two domestic animals had upon the manners of that once timid people. It is eafy to conceive what formidable enemies they must now be to the Spaniards; for supposing them defeated in battle, How is it possible to follow them in such long excursions? How is it possible to prevent assemblages, which bring together in a fingle point nations scattered over 400 leagues of country, and thus form armies of 30,000 men ?"

Of these people M. Rollin, surgeon-major of the frigate la Buffale, gives the following physiological particulars: "They are, in general (fays he), of lower ftature, and less robust, than Frenchmen, though they endure with great courage the fatigues of war and all its attendant privations. There is a great famenels in the physiognomy of most individuals. The face is larger and rounder than that of Europeans. The features are more ftrongly marked. The eyes are fmall, dull, black, and deeply feated. The forehead is low; the eyebrows black and fhaggy; the nofe fhort and flattened; the cheek-bones high; the lips thick; the mouth wide; and the chin diminutive. The women are short, illmade, and with difgusting countenances. Both men and women bore their note and ears, which they adorn with glass or mother of pearl trinkets. The colour of their skin is a reddish brown: That of their nails is similar, but not to deep. The hair of both is black, coarfe, and very thick. The men have little beard; but their arm-pits and parts of fex are well furnished with hair, which parts, in most of the women, have

none."

The military governor of Conception, who was an Irishman, returned, while M. de la Perouse was there, from the frontiers of the Spanish settlements, where he had just concluded a glorious peace with the Indians. This peace was highly necessary to the people of his government, whose distant habitations were exposed to the inroads of favage cavalry, whose practice it is to maffacre the men and children, and to make the women prisoners. This amiable man, whose name was Higguins (probably Higgins), had succeeded in gaining the good-will of these savages, and thereby rendered the most figual service to the nation that had adopted him. For while the Indians and Spaniards are at variance, an alliance with the former by any of the maritime powers of Europe would become fo formidable to the latter, as to induce them, for fear of their lives, to abandon their fettlements in Chili, and retire to Peru. This was clearly feen by Monneron the engineer on the expedition, who, with the true spirit of a Frenchman, pointed out to his government the method of wresting from its most faithful ally one of the most valuable pro-

vinces of the Spanish empire.

La Perouse describes the common people of Conception as much addicted to thieving, and the women as exceedingly easy of access. "They are a degenerated and mongrel race (fays he); but the inhabitants of the first class, the true bred Spaniards, are polite and obliging in the extreme. The bishop was a man of great fenle, of agreeable manners, and of a charity of which the Spanish prelates afford frequent examples." He was a Creole, and had never been in Europe. Of the monks our author gives a very different character. "The misfortune (fays he) of having nothing to do, the want of family ties, the profession of celibacy, without being separated from the world, and their living in the convenient retirement of their cells, has rendered, and could not fail to render, them the greatest profigates in America. Their effrontery is inconceivable. I have seen some of them stay till midnight at a ball; aloof, indeed, from the good company, and feated among the fervants. Thefe fame monks gave our young men more exact information than they could get elfewhere, concerning places with which priests ought to have been acquainted only in order to interdict the entrance."

M. de la Perouse represents that part of Chili, which is called the Bishopric of Conception, as one of the most fertile countries in the universe. Corn yields fixty to one; the vineyards are equally productive; and the plains are covered with innumerable flocks, which, tho' left to themselves, multiply beyond all imagination. Yet this colony is far from making the progress that might be expected from a fituation fo favourable to an increase of population. The influence of the government incessantly counteracts the climate and the foil. hibitory regulations exist from one end of Chili to the other; and this kingdom, of which the productions, if carried to their highest pitch, would feed the half of Europe; of which the wool would fuffice for the manutactures of Great Britain and France, even when manufactures flourished in the latter country; and of which the cattle, if falted down, would produce an immense revenue-is entirely destitute of commerce, and its inhabitants funk in sloth and indolence. Unless, therefore, Spain change its fystem entirely, Chili will never reach that pitch of prosperity which might be expected from its fituation and fertility. For the latitude and longitude of Conception, see Encycl.
CONDORCET (Jean-Antoine Nicolas Caritat

de), was born at Ribemont in Picardy, the 17th of September 1743, of a noble and very ancient family. At the age of 15 he was fent to study philosophy at the college of Navarre, and had the good fortune to fall into the hands of an able professor, who has since dif-

SUPPL. VOL. I. Part II.

tinguished himself by his geometrical works. The Condorcetyoung Condorcet had no relish for the business of the first course, for the quibbles of ontology and pneumatology, and all the wretched appendages of school metaphysics: But in the following year, his studies, being directed to the mathematical and physical sciences, were entirely congenial to his tafte; and though there were upwards of 120 scholars, he distinguished himself above them all. At Easter he held a public thesis, at which Clairaut, D'Alembert, and Fontaine, affisted. · He now returned home, but continued to cultivate geometry. To enjoy more opportunities of improvement, he removed in 1762 to Paris; where he attended the chemical course of Macquer and Beaume, and frequented the literary focieties which D'Alembert had formed at

the house of Mademoiselle de Lespinasse.

In 1765, when only 22 years old, he published a work on the Integral Calculus, which discovered vast extent and originality of views. Condorcet was already numbered with the foremost mathematicians in Europe. "There was not (fays La Lande) above ten of that class; one at Petersburg, one at Berlin, one at Basle, one at Milan, and five or fix at Paris; England, which had fet fuch an illustrious example, no longer produced a fingle geometer that could rank with the former." It is mortifying to us to confess that this remark is but too much founded in truth. We doubt not but there are in Great Britain at present mathematicians equal in profundity and address to any who have existed since the illustrious Newton; but these men are not known to the learned of Europe, because they keep their science to themselves. They have no encouragement, from the tafte of the nation, to publish any thing in those higher departments of geometry which have so long occupied the attention of the mathematicians on the continent.

In 1767 Condorcet published his folution of the problem of three bodies; and in the following year, the first part of his Analytical Essays; in which he entered very profoundly into those arduous questions. He was received into the academy on the 8th of March 1769; and from that time till 1773 he enriched their annual volumes with memoirs on infinite feries, on partial and finite differences, on equations of condition, and on other objects of importance in the higher calculus. It must be regretted, that he indulged speculation perhaps to excess; the methods that he proposes for integration are sometimes of a nature so extremely general, as to refuse to be accommodated to practice. Prosecuting those researches for several years longer, he composed an ample Treatise on the Integral Calculus, in five parts, comprising the doctrines and their application. It was afterwards copied out for the press in 1785 by Keralio, formerly governor to the Infant of Parma. Only 128 pages were printed; but the manufcript ftill exists; as does that of an elementary Treatise on Arithmetic. It is to be hoped that both of these will yet be given to the public.

His attention was not, however, entirely absorbed in those recondite studies. He published about this time an anonymous pamphlet, intitled a Letter to a Theologian; in which he replied with keen fatire to the attacks made by the author of the Three Centuries of Literature against the philosophical sect. "But (sub joins the prudent La Lande) he pushed the matter

Condorcet fomewhat too far; for, admitting the juffness of his fystem, it was more prudent to confine within the circle of the initiated those truths which are dangerous for the multitude, who cannot replace by found principles what they would lofe of fear, of confolation, and of hope." Condorcet was now leagued with the atheists; and La Lande, who wishes well to the same sect, cenfures not his principles, but only regrets his rashness.

He was indeed, as Mr Burke observed, a fanatic atheist

and furious democratic republican.

On the 10th of June 1773 he was made fecretary of the academy of sciences; and that important trust he discharged through the rest of his life with great ability and uncommon reputation. The duties of his office required him to write the lives of the deceafed academicians, which he performed with diligence, judgment, and univerfal applause: And what species of compofition is capable of being rendered fo extensively useful as biography? In the most infinuating form it conveys instruction; and, bestowing vitality and action on the rules of conduct and on the lessons of virtue, it fires the breast with the noblest emulation. The life of a philosopher must also include a portion of the history of science. We there trace the successive steps which led to discoveries, and learn to estimate the value of those acquisitions by the efforts that were made, and the obstacles that were surmounted. The literati of France have long excelled in the composition of Eloges: but those of Condorcet are of a very superior cast. Replete with information and genuine science, they maintain a dignified impartiality, and display vigour of imagination, with boldness and energy of style. The intrepidity (fay his Panegyrists) with which he uttered the sentiments of truth and of freedom, could not have been expected from the mouth of an academician under an abfolute monarchy. It could not, indeed, till the prefent eventsul age, have been expected under any government whatever; for what he called the fentiments of truth were the dogmas of debafing irreligion, which would not have been permitted in the far-famed republics of Greece and Rome; and what he dignified with the appellation of the principles of freedom, experience has shown to have been the immediate fource of anarchy, out of which has sprung a despotism, the heaviest under which any people have groaned fince the creation of the world.

Besides the eloges, which properly belonged to his province, Condorcet published in a separate volume the lives of those favants, who, having died before the renewal of the academy in 1699, did not fall in with the plan of Fontenelle. The suppression of the history of the academy, or the regular abstracts of the printed memoirs, which he effected in 1783, afforded him more leisure. In 1787 appeared, yet without a name, his account of Turgot; an inestimable piece, which, in developing the beneficial views of a virtuous and enlightened minister, exhibits the neatest abstract of the principles of political economy that is extant in any lan-Nearly about the same time, he composed that elegant life which is prefixed to the splendid edition of the works of Voltaire. Condorcet had been elected member of the academie Française in 1782; and his reputation as a fine writer was fo well established, that booksellers were solicitous to cover their undertakings with the fanction of his name. He promifed an addiGerman Princess; but it was never finished. The part Cond which was printed, amounting to only 112 pages, contains the elements of the calculation of probabilities, and a curious plan of a dictionary, in which objects thould be arranged by their qualities merely. A new translation of Smith's celebrated Wealth of Nations was likewife announced with the notes of Condorcet, tho' he was never heartily engaged about it. On equally flight grounds, his name was lent to the Bibliotheque de l'Homme Public; and the facility of his temper laid him but too open, at this period, to fuch difingenuous arts. Indeed difingenuous arts feem to be the natural offspring of the prefent philosophy of France; for the tricks played by Voltaire to his bookfellers, which are well known, would in this country have funk into difgrace the greatest genius that ever lived; and the attempt of Diderot to cheat the late emprels of Ruffia. by felling to her, at an inmense price, a library, which he pretended to be one of the most valuable in Europe, when he possessed not perhaps one hundred volumes. was difingenuity ingrafted on impudence. But to return from this short digression.

These literary purtuits did not entirely seduce Condorcet from more profound studies. At the instigation of Turgot, he fought to apply analysis to questions of politics and morality. His first Memoir on Probabilities was read to the academy in 1781. He afterward extended his refearches to the confideration of elections, fales, and fuccessions; and digesting those remarks and calculations into a systematic shape, he published in 1785 a quarto volume, containing the elements of a

new and important science.

It is easy to conceive the interest that Condorcet would take in the fuccess of the revolution. Aware of the prodigious influence of newspapers, he contributed largely to the Journal de Paris, and the Chronique, which acquired great celebrity from the elegance of his pen; and not very long before his death, he began, in concert with the famous Sieyes, a Journal of Social Instruction. In 1791 he wrote a pamphlet in favour of republican government, which procured him a feat in the Legislative Assembly, and the academy permitted him still to retain the office of secretary. He drew up a manifesto on the subject of the war menaced by the crowned heads; and a very ample report on public instruction, which has in part been lately adopted by the councils of France. He was an early member of the Jacobin club, that active instrument of the revolution: but perceiving the progressive ferocity of its measures, he forfook it in March 1792.

On the 13th of August, when the king was conducted to the temple, Condorcet was named by the Affembly to draw up a justificatory memorial addressed to all Europe. At the diffolution of that Affembly, he was chosen deputy to the National Convention, and for fome time acted a diftinguished part in its deliberations. He was at the head of the committee appointed to prepare the plan of a republican constitution. But, in the meanwhile, the faction of the Mountain, with a peculiar energy of character, was rapidly acquiring strength. The report of the committee was coldly received - was even treated with contempt; and, on the 31st of May 1793, Robespierre completely triumphed. The Briffotins were arrested, outlawed, dispersed; and Condortional volume to the translation of Euler's Letters to a cet, having voted against the death of the king, was innd et volved in the proscription. For some months he obtained an afylum at Paris in the house of a woman, who was ignorant of his person, but commiserated his lot. Nothing, however, could elude the vigilance of the tyrant. Menaces of a strict domiciliary visit compelled him at last, in March 1794, to quit his concealment. He escaped the barriers, and passed the first night in the plain of Montrouge. On the next morning, he repaired to the house of an old friend at Fontenai, who most unfortunately had gone to Paris, and was not ex. peded to return for two days. In this deplorable state of suspense did Condorcet pass one night in a quarry, and another under a tree in the fields. On the third day he hastened to meet his friend; but the meeting was short and unsatisfactory. After a hasty refreshment, it was agreed that he should depart in the meanwhile, to return again at night after all the fervants were retired to reft. He was therefore obliged to wander about the neighbourhood of Clamar. Exhausted with hunger and fatigue, and his feet terribly bruised, nature could hold out no longer. He entered an alehouse, where his long beard and haggard looks exposed him to suspicion. A member of the revolutionary committee of Clamar demanded his paffport, led him away to the committee, and thence transferred him to the district of Bourg-la-Reine. Having arrived too late for interrogation, he was shut up in prison under the name of Pierre Simon, with the intention of being fent to Paris. On the 28th of March he was found dead.

Thus miserably perished a most able philosopher, and one of the finest writers of those that have adorned the prefent century. His private character is described by La Lande as easy, quiet, kind, and obliging; but his behaviour to Diderot when dying, displayed, instead of the milk of human kindness, the malignity of a fiend. Neither his conversation nor his external deportment befpoke the fire of his genius. D'Alembert used to compare him to a volcano covered with fnow. He had a latent weakness, however, of constitution, which often made him the dupe of men altogether unworthy of his

regard.

It was during the period of his concealment at Paris, uncertain of a day's existence, that he wrote his Sketch of the Progress of the Human Mind; a production which undoubtedly displays genius, though it contains some of the most extravagant paradoxes that ever fell from the pen of a philosopher. Among other wonderful things, the author inculcates the possibility, if not the probability, that the nature of man may be improved to absolute perfection in body and mind, and his existence in this world protracted to immortality. So firmly does he feem to have been perfuaded of the truth of this unphilosophical opinion, that he fet himfelf feriously to confider how men should conduct themselves when the population should become too great for the quantity of food which the earth can produce; and the only way which he could find for counteracting this evil was, to check population by promiscuous concubinage and other practices, with an account of which we will not fully our pages. Yet we are told by La Lande, that this sketch is "only the outline of a great work, which, had the author lived to complete it, would have been considered as a monument erected to the honour of human nature!!!" La Lande, indeed, speaks of the

author in terms of high respect; and his abilities are Conserva certainly unquestionable: but what shall we think of the morals of that man, who first pursued with malicious reports, and afterwards hired ruffians to affaffi . * Your. de nate *, the old Duke of Rochefoucalt, in whose house Ply! Nov. he had been brought up; by whom he had been treat-1792. ed as a fon; and at whole folicitation Turgot created for him a lucrative office; and by the power of the court raifed him to all his eminence? There is a living English writer, who has laboured hard to prove that gratitude is a crime. Condorcet must surely have held the same opinion; and therefore could not blame those low born tyrants who put him to death by what we would call an unjust sentence; for it was in some degree to his writings that those tyrants were indebted for their

About the end of the year 1786, Condorcet married Marie Louise Sophie de Grouchy, whose youth, wit, and beauty, were less attractive in the eyes of a philofopher than the tender and courageous anxiety with which the watched the couch, and affuaged the fufferings, of the fon of the prefident du Paty, who had been bitten by a mad dog. This union, however, we are told, was fatal to his repose; it tempted him into the dangerous road of ambition; and the idea of providing for a wife and daughter induced him to feek for offices

which once he would have detpifed.

CONFERVA JUGALIS (lee Conferva Encycl.) is introduced here merely on account of a curious circumflance respecting it, which was communicated, not long ago, to the Philomatic Society at Paris. Citizens Charles and Romain Coquebert having collected fome of this Conferva in the neighbourhood of Paris, afcertained, by means of an excellent microscope, constructed by Nairne and Blunt, that, in this species, there are male and female filaments, which unite by an actual copulation; that certain globules contained in the male filaments pass into the interior part of the female filaments; and that by this union there are formed in the latter feeds, or, if we may use the expression, small ova, which reproduce the species. This is the first instance, in the vegetable kingdom, of a reproduction absolutely analogous to that which we find among animals. Philosophical Magazine, no 3.

May this fact be depended on We question not, in the flightest degree, the veracity of the editor of the very respectable miscellany from which we have copied it; but we confess ourselves inclined to admit the phyfiological discoveries of citizen philosophers with great helitation. The fact, if real, is certainly curious, and may lead to important conclusions; and we therefore recommend an investigation of its truth to our botanical

CONCELATION, see CHEMISTRY in this Sup-

plement, n° 280-283.

CONTAGION (see Encycl.) is a subject on which much has been written to very little purpose. Of all the attempts which have been made to account for it, there is not one that can be thought fatisfactory. This, however, is not perhaps a matter of great importance, if a method could only be discovered to stop the progress of contagion where it is known to have place. Among the many benefits which may be reaped from the late discoveries in Chemistry, even this desideratum

Contagion, promises to be one; and we surely need not add one of the greatest. Dr James Carmichael Smyth, physician extraordinary to his Majesty, suggested, in the year 1795 or 1796, a process for determining the effect of the nitric acid in destroying contagion; and experiments, according to his directions, were made on board the Union and other ships at Sheerness.

The Union was an hospital ship, and the experiment on board her was conducted by Mr Menzies, late furgeon to his Majesty's sloop Discovery, and by Mr Basfan, surgeon of the Union; and when it is considered, that fresh contagion was daily pouring into the hospital from the Ruffian veffels, which were at that time lying in the Downs, and which had brought with them a species of fever that might in every sense of the word be termed an epidemy, it will be allowed, that the fuccess which attended it was such that it cannot be too generally known.

The wards were extremely crowded, and the fick of every description lay in cradles, promiscuously arranged, to the number of nearly two hundred; of which, about one hundred and fifty were in different stages of the above malignant fever, which was extremely contagious, as appeared evident from its rapid progress and fatal effects among the attendants on the fick and the

ship's company.

were the following: A quantity of fine fand, about two dozen quart earthen pipkins, as many common teacups, some long slips of glass to be used as spatulas, a quantity of concentrated vitriolic (fulphuric) acid, and

a quantity of pure nitre (nitrat of potash).

The process was conducted in the following manner: 1/f, All the ports and scuttles were shut up; the fand, which had been previously heated in iron pots, was then scooped out into the pipkins by means of an iron ladle; and in this heated fand, in each pipkin, a fmall tea-cup was immerfed, containing about half an ounce of the fulphuric acid, to which, after it had acquired a proper degree of heat, an equal quantity of nitrat of potash in powder was gradually added, and the mixture stirred with a glass spatula till the vapour arose from it in confiderable quantity (A). The pipkins were then carried through the wards by the nurses and convalescents, who kept walking about with them in their hands, occasionally putting them under the cradles of the fick, and in every corner where any foul air was suspected to lodge. In this manner they continued fumigating, until the whole space between decks was fore and aft filled with the vapour, which appeared like a thick haze.

The vapour at first excited a good deal of coughing among the patients, which gradually ceased as it became more generally diffused through the wards: part of this effect, however, was to be attributed to the inattention of those who carried the pipkins, in putting them too near the faces of the fick; which caused them to inhale the strong vapour as it immediately issued from

the cups.

The body-clothes and bed-clothes of the fick were, Co as much as possible, exposed to the nitrous vapour during the fumigation; and all the foul linen removed from them was immediately immerfed in a tub of cold water, afterwards carried on deck, rinfed out, and hung up till nearly dry, and then fumigated before it was taken to the wash-house: a precaution extremely necesfary in every case of infectious diforder. Due attention was also paid to cleanliness and ventilation.

It took about three hours to fumigate the ship. In about an hour after, the vapour having entirely subfaded, the ports and fcuttles were thrown open for the admission of fresh air. It could plainly be perceived that the air of the hospital was greatly sweetened even by this first fumigation. The process was repeated again next morning; and the people employed, being now better acquainted with it, were more expert, and finished the whole in about an hour's time. In an hour afterwards, the vapour having entirely subsided, the fresh air was freely admitted into the hospital as before. Fewer pipkins were employed for the evening fumigations than for those of the mornings, as the fresh air could not be admitted fo freely after the former as the latter.

The pleafing and immediate effect of the fumigation in destroying the offensive and disagreeable smell, arising The utenfils and materials provided for the process from so many sick crowded together, was now very perceptible, even to the nurses and attendants; the confequence of which was, that they began to place fome degree of confidence in its efficacy, and approached the cradles of the infected with less dread of being attacked with the disorder: so that the fick were better attended, and the duty of the hospital was more regularly and more cheerfully performed. In short, a pleasing gleam of hope feemed now to cast its cheering influence over that general despondency, which was before evidently pictured in every countenance, from the dread and horror each individual naturally entertained of being, perhaps, the next victim to the malignant powers of a virulent contagion.

It is a remarkable fact, that from the 26th of November 1795, when the fumigation was first resorted to, till the 25th of December, not a person on board was attacked with the fever, though, in the three months preceding, more than one third of all the people in the ship had been seized with the distemper, and of these more than one in four were carried off by it; and the probability is, that the fickness and mortality would have gone on, increasing in proportion to the diffusion of the contagion, and to the increasing despondency of the people, who considered themselves as so many devo-

The advantage of the fumigation was not felt by the ship's company and attendants alone, whom it preserved from the baneful effects of the fever: the fick and convalescents derived almost an equal benefit from it. The fymptoms of the difease were meliorated, and lost much of their malignant appearance; and the advantage of a

⁽A) That the fumes of the mineral acids possessed the property of stopping contagion was proved by Morveau as far back as the year 1773, who, by means of the fumes of muriatic acid extricated from the muriat of soda (fea falt) by the sulphuric acid, purified the air of the cathedral of Dijon, which had been so much infected by exhumations that they were obliged to abandon the building. See CHEMISTRY, no 426, in this Supplement.

ntain pure air, and free from stench, to convalescents, may be

readily conceived.

Great confidence is always dangerous. It proved fo on the present occasion. On the 17th of December they imagined themselves so secure, that they discontinued the custom of fumigating morning and evening, thinking that once a day was sufficient. On the 25th, thinking that once a day was fufficient. one of the nurses suffered a slight attack; and on the 26th, a marine, who, for a week before, had been in a state of intoxication, was seized with the fever, of which he died. These two accidents gave immediate alarm: they returned again to the practice of fumigating twice a day; and from that time to the extermination of the disorder, there was not an instance of a person suffering from contagion on board the ship.

The success of the experiment was not confined to the Union: the power of the nitrous vapour to destroy contagion was equally displayed on board the Russian ships in which it was employed. The safety, too, with which it may be employed, in any fituation, without inconvenience or risk of fire, is another great recom-

mendation in its favour.

From the description that has been given of the process, no person can be at any loss in resorting to the fame kind of fumigation. It is only necessary to obferve, for the fake of those who may not be verfant in chemical pursuits; that the ingredients ought to be pure, and that metal veffels or rods must not be employed. Any kind of metal getting among the ingredients would cause the vapour to be very noxious instead of falutary. The fumes that rife should be white; if they are of a red colour, there is reason to suspect the

purity of the ingredients.

The importance of this discovery need not be infifted on: it is equally applicable to every species of putrid contagion, even to the plague itself. It should therefore be used in all hospitals and parish workhouses; and should be constantly resorted to by the proprietors of all large works, on the first appearance of infectious disease among the people employed in them :- indeed, it should be employed even as a preventive in all fituations where a number of people, from the nature of their business, are obliged to be crowded together, or where, from local circumstances, there are reasons for suspecting that the purity of the air is injured by noxious exhalations or other causes. If there be any circumstances in which its utility may be called in question, it can only be in cases of inflammatory diseases; for, in such, superoxygenation has been found hurtful

CONTRA-HARMONICAL Proportion, that relation of three terms, in which the difference of the first and fecond is to the difference of the fecond and third, as the third is to the first. Thus, for instance, 3, 5, and 6, are numbers contra-harmonically proportional; for

CONTRA-Mure, in fortification, is a little wall built before another partition wall, to strengthen it, so that it may receive no damage from the adjacent buildings.

COOPER, an artificer who makes coops, casks, tubs, or barrels, i. e. all kinds of wooden veffels bound

together by hoops. See Encycl.

The art of the cooper appears to be of great antiquity, and to have very foon attained to all the perfection which it possesses at present. This being the case,

it is obvious that we can communicate no instruction to Cooper. the cooper himself, and, on the subject of his art, very little that could be interesting to our other readers. In the Encyclopedie Methodique there is a long and verbose account of the tools or inftruments employed by the cooper; of the kinds of timber proper for the different kinds of casks; of the methods of preparing the wood for his various purpofes; of the manner in which he ought to hold the plane when dreffing the staves; and of the time when it is proper to put the staves together, or, in other words, to mount the cask. From this detail we shall extract such particulars as appear to us to be least generally known, though perhaps of no great

importance in themselves.

Notwithstanding the antiquity of the art of caskbuilding, there are fome countries in which even now it is wholly unknown; and others where, though it is fufficiently known, yet, from the scarcity of wood or some other cause, earthen vessels, and skins lined with pitch, are preferred to wooden barrels for the holding and transporting of liquors. The Latin word dolium, which we translate "a cask," was employed by the Romans to denote earthen veffels used for this purpose; though the word dolare, from which it is derived, applies very well to our casks, which are composed of several pieces of wood hewn from the same tree, and fitted by planes before they be joined together. We are indeed certain that casks of the same kind with our own were in use among the Romans before the Chriftian era; for both Varro and Columella, in treating of the rural economy of their days, speak of vessels formed of feveral flaves of wood bound together by circles or hoops. The merit of having invented fuch veffels is given by Pliny to certain people who lived at the foot of the Alps, and who in his days lined their casks with

At what period the fabrication of casks was introduced into Britain is unknown to us, though it is probable that we derived the art from the French, who might

have it from the Romans.

We need hardly inform any of our readers, that a cask has the appearance of two truncated cones joined at their bases, or that the part where the junction appears to be made being the most capacious, or that of which the diameter is the largest, is vulgarly called the belly of the cask. These cones, however, were they completed, would not be regular, but rather conoids, being formed of pieces of timber, or staves, which are not ftraight lines as in the cone, but are curved from the vertex to the base.

In choosing his wood, if he can have a choice, the cooper prefers old and thick and straight trees, from which he hews thin planks to be formed into staves; and in France, where this art is practifed on a large scale, the winter months are allotted for the preparation of the staves and bottoms, and the summer for putting them together or mounting the cask. The author of the article in the Encyclopedie Methodique directs the cooper, when dreffing the staves with the plane, to cut the wood always across; a practice which we doubt not is proper, though we think it would not be eafy to affign the reason of it. Plaining is the most laborious and difficult part of the work; and there are but few coopers who plane quickly, and at the same time well.

Cooper. In shops where the work is distributed into parts, plaining is reckoned a great object; and in France, before the revolution, a good plainer gained from three shillings and threepence flerling to four shillings and three

farthings a-day.

In forming the staves, it must never be forgotten that each is to constitute part of a double conoid; that it must therefore be broadest at the middle, becoming gradually, though not in straight lines, narrower towards the extremities; that the outfide across the wood must be wrought into the fegment of a circle; an! that the flave must be thickest near the middle, growing thinner, by very gentle degrees, towards the ends. To adjust accurately these different curves (for even the narrowing of the staves must be in a curve) to the fize and intended shape of the cask, would require either great experience, or a larger portion of mathematical science than we have reason to think that many coopers posfels. With respect to the infide of the stave, it is of little consequence whether it be rounded into the segment of a circle or not, and therefore the cooper very feldom takes that trouble.

The staves being all dressed and ready to be arrauged in a circular form, it might be thought necessary, in order to make the seams tight, to trim the thin edges, which are to be joined together, in fuch a manner as that a ray passing from the outside of the cask through a feam to the centre, should touch the contiguous staves from the exterior to the interior fide; in other words, that the thin edges should be sloped as the archstones of a bridge are sloped, so that the contiguous staves may be brought into firm contact throughout the whole joint. This, however, is not the practice of the cooper. With great propriety he brings the contiguous staves into contact at their inner surfaces only; fo that by driving the hoops hard, he can make the joints much closer than he could possibly have done had the edges of the staves been so sloped as to permit them to touch each other throughout before being drove together by the compression of the hoops. This, together with giving to the staves the proper curvature, feems to be the only part of the cooper's work which deserves the name of art; for the driving of the hoops and the forming of the bottoms could certainly be accomplished by any carpenter, we had almost faid by any man, though he had never feen a hoop driven or a bottom formed.

In many parts of Scotland, instead of ale or beer mugs, they use small hooped wooden veffels, of which the staves are feather-edged or dove-tailed into one another. This, as the staves are of different colours, increases the beauty of the vessel, and to a superficial obferver appears to be an ingenious contrivance; but it adds nothing to the strength or tightness of the seam, and cannot be attended with the smallest difficulty. We think, indeed, that in a large cask or tub it would prove injurious to the seam; for either these dove-tails must be very thin slips raised from the interior edges of the staves, which in many cases could not be done if the wood were thoroughly seasoned; or if they be cut out like inverted wedges, the contiguous staves must be brought into contact from the interior to the exterior fide previous to the driving of the hoops; and in that cafe, as we have feen, the feams could not be made completely tight.

COPERNICUS (Nicolaus), the restorer, if not the Cop. inventor, of the true system of the sun, holds so conspicuous a place in the republic of science, that every man of a liberal education must be interested both in the events of his life and in the history of his discoveries. Accordingly, in the Encyclopædia, we have given a short sketch of his history, as well as an account of what led him to suppose the sun placed in the centre of our fystem (see Copernicus, and Astronomy, no 22. Encycl.) Since these articles were published, Dr. Adam Smith's Essays on Philosophical Subjects have been given to the world; and in that which is intitled The History of Astronomy, we have an account of Copernicus's difcoveries, so much more perspicuous and satisfactory than any thing which we have elsewhere seen on the subject, that we are persuaded our readers will be pleased to meet with it here.

" The confusion (fays Dr Smith) in which the old hypothesis represented the heavenly bodies, was, as Copernicus himself teils us, what first suggested to him the delign of forming a new system, that these, the noblest works of Nature, might no longer appear devoid of that harmony and proportion which discover themselves in her meaneit productions. What most of all dissatisfied him was, the notion of the equalizing circle, which, by representing the revolutions of the celestial spheres as equable only, when furveyed from a point that was different from their centres, introduced a real inequality into their motions; contrary to that most natural, and indeed fundamental idea, with which all the authors of astronomical systems, Plato, Eudoxus, Aristotle, even Hipparchus and Ptolemy themselves, had hitherto set out, that the real motions of fuch beautiful and divine objects must necessarily be perfectly regular, and go on, in a manner as agreeable to the imagination as the objects themselves are to the senses. He began to consider, therefore, whether, by supposing the heavenly bodies to be arranged in a different order from that in which Ariftotle and Hipparchus had placed them, this so much fought for uniformity might not be bestowed upon their motions. To discover this arrangement, he examined all the obscure traditions delivered down to us, concerning every other hypothesis which the ancients had invented, for the same purpose. He found, in Plutarch, that some old Pythagoreans had represented the earth as revolving in the centre of the universe, like a wheel round its own axis; and that others, of the same feet, had removed it from the centre, and represented it as revolving in the ecliptic like a star round the central fire. By this central fire he supposed they meant the fun; and though in this he was very widely mistaken, it was, it feems, upon this interpretation that he began to confider how fuch an hypothef:s might be made to correspond to the appearances. The supposed authority of those old philosophers, if it did not originally fuggest to him his fystem, seems at least to have confirmed him in an opinion which, it is not improbable, he had before-hand other reasons for embracing, notwithstanding what he himself would affirm to the con-

if It then occurred to him, that if the earth was supposed to revolve every day round its axis, from west to east, all the heavenly bodies would appear to revolve, in a contrary direction, from east to west. The diurnal revolution of the heavens, upon this hypothesis, might

pernicus be only apparent; the firmament, which has no other fensible motion, might be perfectly at rest; while the fun, the moon, and the five planets, might have no other movement befide that eaftward revolution which is peculiar to themselves That, by supposing the earth to revolve with the planets round the fun, in an orbit, which comprehended within it the orbits of Venus and Mercury, but was comprehended within those of Mars, Jupiter, and Saturn, he could, without the embarrassment of epicycles, connect together the apparent annual revolutions of the fun, and the direct, retrograde, and stationary appearances of the planets; that while the earth really revolved round the fun on one fide of the heavens, the fun would appear to revolve round the earth on the other; that while she really advanced in her annual course, he would appear to advance eastward in that movement which is peculiar to himself. That, by supposing the axis of the earth to be always parallel to itself, not to be quite perpendicular, but somewhat inclined to the plane of her orbit, and confequently to prefent to the fun, the one pole when on the one fide of him, and the other when on the other, he would account for the obliquity of the eeliptic; the fun's feemingly alternate progression from north to fouth, and from fouth to north, the confequent change of the feafons, and different lengths of days and

nights in the different seasons. " If this new hypothesis thus connected together all these appearances as happily as that of Ptolemy, there were others which it connected together much better. The three superior planets, when nearly in conjunction with the fun, appear always at the greatest distance from the earth, are smallest, and least sensible to the eye, and feem to revolve forward in their direct motion with the greatest rapidity. On the contrary, when in opposition to the fun, that is, when in their meridian about midnight, they appear nearest the earth, are largest, and most sensible to the eye, and seem to revolve backwards in their retrograde motion. To explain these appearances, the fystem of Ptolemy supposed each of these planets to be at the upper part of their feveral epicycles in the one case, and at the lower in the other. But it afforded no fatisfactory principle of connection, which could lead the mind eafily to conceive how the epicycles of those planets, whose spheres were so distant from the sphere of the fun, thould thus, if one may fay so, keep time to his motion. The system of Copernicus afforded this easily, and like a more simple machine, without the affiltance of epicycles, connected together, by fewer movements, the complex appearances of the heavens. When the superior planets appear nearly in conjunction with the fun, they are then in the fide of their orbits, which is almost opposite to, and most distant from, the earth, and therefore appears smallest and least sensible to the eye. But as they then revolve in a direction which is almost contrary to that of the earth, they appear to advance forward with double velocity; as a ship that sails in a contrary direction to another, appears from that other to fail both with its own velocity and the velocity of that from which it is feen. On the contrary, when those planets are in opposition to the sun, they are on the same side of the sun with the earth, are nearest it, most sensible to the eye, and revolve in the same direction with it; but as their

revolutions round the fun are flower than that of the Copernicus. earth, they are necessarily left behind by it, and therefore feem to revolve backwards; as a hip which fails flower than another, though it fails in the fame direction, appears from that other to fail backwards. After the same manner, by the same annual revolution of the earth, he connected together the direct and retrograde motions of the two inferior planets, as well as thestationary appearances of all the five.

"Thus far did this new account of things render the appearances of the heavens more completely coherent than had been done by any of the former fysteras. It did this, too, by a more simple and intelligible, as well as more beautiful machinery. It represented the fun, the great enlightener of the universe, whose body was alone larger than all the planets taken together, as established immoveable in the centre, shedding light and heat on all the worlds that circulated around him in one uniform direction, but in longer or shorter periods, according to their different distances. It took away the diurnal revolution of the firmament, whose rapidity, upon the old hypothesis, was beyond what even thought could conceive. It not only delivered the imagination from the embarraffment of epicycles, but from the difficulty of conceiving these two opposite motions going on at the same time, which the tystem of Ptolemy and Aristotle bestowed upon all the planets; I mean, their diurnal westward, and periodical eastward revolutions. The earth's revolution round its own axis took away the necessity for supposing the first, and the second was eafily conceived when by itself. The five planets, which feem, upon all other systems, to be objects of a species by themselves, unlike to every thing to which the imagination has been accustomed, when supposed to revolve along with the earth round the fun, were naturally ap. prehended to be objects of the same kind with the earth, habitable, opaque, and enlightened only by the rays of the fun. And thus this hypothesis, by classing them in the same species of things, with an object that is of all others the most familiar to us, took off that wonder and uncertainty which the strangeness and fingularity of their appearance had excited; and thus far, too, better answered the great end of philosophy.

" Neither did the beauty and implicity of this fystem alone recommend it to the imagination: the novelty and unexpectedness of that view of nature which it opened to the fancy, excited more wonder and furprife than the thrangest of those appearances, which it had been invented to render natural and familiar, and thefe fentiments fill more endeared it. For though it is the end of philosophy to allay that wonder which either the unufual or feemingly disjointed appearances of nature excite, yet the never triumphs fo much as when, in order to connect together a few, in themselves perhaps inconsiderable objects, she has, if I may say so, created another constitution of things, more natural indeed, and fuch as the imagination can more easily attend to, but more new, more contrary to common opinion and expectation, than any of those appearances themselves. As in the instance before us, in order to connect together fome feeming irregularities in the motions of the planets, the most inconsiderable objects in the heavens, and of which the greater part of mankind have no occasion to take any notice during the whole course of their lives,

Dopper. Brahé, moved the earth from its foundations, stopt the revolution of the firmament, made the fun stand still, and

Subverted the whole order of the universe.

" Such were the advantages of this new hypothesis, as they appeared to its author when he first invented it. But though that love of paradox, fo natural to the learned, and that pleafure which they are fo apt to take in exciting, by the novelty of their supposed discoveries, the amazement of mankind, may, notwithstanding what one of his disciples tells us to the contrary, have liad its weight in prompting Copernicus to adopt this system; yet when he had completed his Treatife of Revolutions, and began coolly to confider what a strange doctrine he was about to offer to the world, he fo much dreaded the prejudice of mankind against it, that, by a species of continence of all others the most difficult to a philo-Sopher, he detained it in his closet for thirty years together. At last, in the extremity of old age, he allowed it to be extorted from him, but died as foon as it was

printed, and before it was published." This noble theory, however, being repugnant to the prejudices of habit and education, was at first coldly received, or utterly rejected, by every class of men. The aftronomers alone favoured it with their notice, though rather as a convenient hypothesis than an important truth. By the vulgar it was confidered as a chimera, belied by the clearest evidence of our senses; while the learned beheld it with difdain, because it militated against the fanciful diffinctions and the vague erroneous tenets of the Peripatetic philosophy, which no one had ventured to call in question; and it is amusing to obferve with what dexterity the Copernicans, still using the fame weapons, endeavoured to parry the blows of their antagonists. Its real merits and blemishes appear to have been overlooked by both parties. Brahé framed a fort of intermediate system; but this Danish aftronomer was more remarkable for his patience and skill in observing the heavens, than for his talents of philosophical investigation. Towards the commencement of the 16th century, a new order of things emerged. The fystem of Copernicus became generally known and daily made converts. Its reception alarmed the ever-watchful authority of the church, roused her jealoufy, and at length provoked her vindictive artillery. The ultima ratio theologorum was pointed at the head of the illustrious Galileo, whose elegant genius discovered the laws of motion, extended the science of mechanics, and added luftre and folidity to the true fystem of the universe. From the storms of persecution Copernicus himself had been exempted only by a timely death.

COPPER, one of the metals; for the properties of which, fee CHEMISTRY-Index in this Supplement .-The Chinese have a metal which they call pe-tung, but

which Sir George Staunton denominates

White Copper. This metal has a beautiful filverlike appearance, and a very close grain. It takes a fine pelish, and many articles of neat workmanship, in imitation of filver, are made of it. An accurate analysis has determined it to confist of copper, zinc, a little filver; and in some specimens a few particles of iron and of nickel have been found. From this account it would appear that white copper is not an artificial mixture of metals, but is found native in the mine. Yet in the very same page and paragraph, Sir George proceeds to

456 Corervicus, she has, to talk in the hyperbolical language of Tycho fay that Dr Gillan was informed at Canton, that the Co artists, in making their pe-tung, reduce the copper in. Con to as thin flieets or laminæ as possible, which they make red hot, and increase the fire to fuch a pitch as to soft. en in some degree the laminæ, and to render them ready almost to flow. In this state they are suspended over the vapour of their pureft tu-te-nag or zinc, placed in a fublining veffel over a brifk fire. The vapour thus penetrates the heated laminæ of the copper, so as to remain fixed with it, and not to be eafily diffipated or calcined by the succeeding fusion it has to undergo. The whole is suffered to cool gradually, and is then found to be of a brighter colour, and of a closer grain, than when prepared in the European way. Surely this is not the white copper, which confifts of copper, zinc, filver, iron, and nickel.

CORK is the exterior bark of a tree which has been described in the Encyclopælia. When the tree is about 15 years old it is fit to be barked, and this can be done fuccessively for eight years. The bark always grows up again, and its quality improves as the age of the tree increases. It is commonly singed a little over a ftrong fire or glowing coals, or laid to foak a certain time in water, after which it is placed under stones in order to be pressed straight. We were wont to procure the greater part of our cork from the Dutch, who brought it principally from France; but they imported

fome also from Portugal and Spain.

This tree, as well as the uses to which its bark is put, was known to the Greeks and the Romans; by the former of whom it was called gealog, and by the latter fuber. By the Romans, as we learn from Pliny, it was even employed to stop vessels of every kind; but its application to this use feems not to have been very common till the invention of glass bottles, of which Professor Beckmann finds no mention before the 15th

century.

In later times, some other vegetable productions have been found which can be employed instead of cork for the last-mentioned purpose. Among these is the wood of a tree common in South America, particularly in moist places, which is called there monbin or monbain, and by botanists spondias lutea. This wood is brought to England in great abundance for that use. The spongy root of a North American tree, known by the name of nyssa, is also used for the same end, as are the roots of liquorice, which on that account is much cultivated in Sclavonia, and exported to other countries.

CORNUA Ammonis, in natural history, arc fossil shells, of which a pretty full account is given in the Encyclopædia. See Cornu Ammonis and SNAKE-Stones. It was observed in the last of these articles, that few, if any, of these shells are known in their recent state, or as occupied by the living animal; but fome authors have afferted, on the authority of Linnæus, that ammonites, with shells similar to all the varieties of the fossil ones, are yet found alive in the depth of the sea. We are much inclined to embrace this opinion; but it has been controverted by M. de Lamanon, who accompanied La Perouse on his voyage of diseavery, by fuch arguments as we know not how to anfwer. This unfortunate naturalist (fee LAMANON in this Supplement) allows that there are still in the sea living cornua ammonis; but he thinks that they are in very small numbers, and materially different from the

greater part of the fossil ones. According to him, these last ought to be confidered as a race, formerly the most numerous of all, of which, either there are no descendants, or those descendants are reduced to a few degenerate individuals. That there are no living animals with shells of the very same kind with some of the fossil cornua ammonis, the following observations he considers

as a sufficient proof.

"The fossil shells are very light and thin, whereas the shells of those animals that live in very deep water are always thick and ponderous; befides, the form of the fossil cornua ammonis points out to us, in some meafure, the organization of the animal which inhabited it. The celebrated Justieu proved, in 1721, that there existed a very close analogy between the ammonite and nautilus (a). It is well known that the nautilus, by filling or emptying a part of its shell, has the power of remaining stationary in any depth it pleases: the same was doubtless the case with the ammonite; and if this species still abounds in the sea, it would furely be occa-

fionally discovered by failors. "The waves also would throw fragments of it on the shore; fishermen might sometimes entangle it in their nets; or, a least, there would be fragments sticking to the lead of the founding line when afcertaining great depths. It may also be added, that if the ammonites never quitted the abyss of the sea, those which are found petrified would not be constantly met with on the same level, and in the same bed, as those shell fish that only inhabit the shallows. There are, however, found in Normandy, Provence, Touraine, and a multitude of other places, ammonites mixed with turbines, buccina (whelks), and other littoral shells. They are found, belides, at every degree of elevation from below the level of the sea to the summits of the highest mountains. Analogy also leads us to suppose, that Nature, who has given eyes to the nautilus, has not refused them to the ammonite; now what use could these be of if they remained confined to those depths which the light is unable to penetrate?

"The extinction of the ancient race of ammonites is therefore an established fact, which no rational suppofition can destroy; and this fact is undoubtedly the most furprifing of any that is presented to us in the history of aquatic animals. The discovery of a few living species of cornua ammonis does not destroy the truth of this, for these ammonites are very different from those which are found petrified. They are extremely rare, and cannot be looked up to as the representatives of the old ammonites, fo varied in their species, and the number of which in the ancient ocean was probably far more confiderable than that of all the other shells

To every univolve shell, rolled in a spiral, so as that a horizontal plane will divide it into two equal parts, formed of united spirals, and bearing a certain proportion to each other, our author gives the name of an ammonite. " I thought it absolutely necessary (fays he) to ascertain the precise meaning of the term ammonite, pre-

SUPPL. VOL. I. Part II.

vious to describing that which I found during our voy- Cornus. age round the world. 'I'he form of this is almost orbicular, the long diameter being to the short one as three lines to two lines and three quarters. The first spire is by far the largest, occupying nearly half of the longitudinal diameter. The fummit is placed at the distance of about two-thirds of this diameter; it is terminated on the right fide by a very small knob visible only through a magnifier, thus differing from the ammonite of Rimini, which belides is microscopical and celled, the infide of this which we are now speaking of being entirely plain. The number of spiral circumvolutions is four and a half; they are equally convex on both fides, and are fixed on a plane, dividing the shell into two equal parts: there is on each fide a kind of bols formed by the increase of the perpendicluar diameter of the spires, in proportion as they recede from the centre. The furface is smooth; the back is armed with a flat, even, brittle crest, as thin as paper, furrounding it on every fide like a ruff: it is about half a line broad, extends over the fummit of the spires, and ferves to join them together. The mouth of the shell is nearly triangular; its edges project in the form of lips, and are rounded at the border. I have often found this ammonite enclosed in the stomach of the bonetta (scomber pelamis, Linn.), caught in the South Sea, between the tropics, where no bottom was found with a line of more than two hundred fathoms. These shells were covered with a black clayey mud. Their fize varies from one to four lines across; they are confequently the largest living ammonites that have yet been discovered."

It is well known for what purpose the modern philosophers of France have been so indefatigable in the study of natural history; and there can be little doubt but that it is to ferve the same purpose that Lamanon thus reasons for the destruction of the ancient race of ammonites in some universal convulsion of the world. But supposing his arguments conclusive, they affect not the truth of the Jewish and Christian scriptures. It is nowhere faid in the Bible, that the matter of this globe was brought into being at the moment when Moses represents the Creator as beginning to reduce the chaos into order; and it is more than infinuated that there will be a new earth after the present system of things shall be dissolved. That new earth will certainly be flored with some kind of inhabitants; and could it be demonstrated that there was an old earth, previous to the era of the Mosaic cosmogony, inhabited by creatures rational and irrational, and that the fosfil cornua ammonis make part of the wreck of that fystem, the cause of revelation would remain uninjured. "Moses, as a real philosopher * has well observed, writes the history, not * Professor of this globe through all its revolutions, but of the race Robifo of Adam."

This fecret attack, therefore, made by Lamanon against that religion of which he once professed to discharge the duties of a priest, is nothing more than te-

lum imbelle sine iclu. Yet it may be worth some natu-3 M ralift's

(A) There are, however, some striking internal differences: first, the partitions in the shell of the nautilus are more curved than those of the ammonite: fecondly, the ammonite wants the small hole which communicates from one cell to the other.

Correction ralist's while to enquire, whether, though feeble, it has been fairly made. We confess that our own suspicions of unfair dealing are strong; for when a man of science contradicts himself in the course of two pages, the blunder must be attributed to some other source than mere inadvertency. M. de Lamanon wishes to prove, among other things, that the ancient ammonites did not inhabit great depths of the fea; and that Linnæus was miftaken when he supposed that in great depths they may still be found. Yet he himself tells us, that he frequently caught ammonites in the South Sea, where no bottom was to be found with a line of more than 200 fathoms; and to put it beyond a doubt that the animals had been at that bottom, he informs us, that their shells were covered with a black clayey mud. It is true these ammonites were but small; while of 300 varieties of fossii ammonites which he mentions, some, he fays, have been found ten feet in circumference. But is it certain that these large shells were real cornua ammonis? If they agree not exactly with our author's description of the shell of the ammonite (a fact into which we have had no opportunity of inquiring), his arguments for the extinction of the ancient race are gross sophisms, unworthy of a man either of science or of candour.

CORRECTION-House is a prison where idle vagrants are compelled to work, and where perfons guilty of certain crimes fuffer punishment and make reparation to the public. Of the former kind of correction-houses, perhaps enough has been faid in the Encyclopædia under the title Work-House; but of the latter very little will be found in that work under the titles BRIDEWELL

and IDLENESS.

Perhaps houses of correction, as means of punishment, are not, in this country, employed fo frequently as justice and expediency seem to require. In the opinion of Dr Paley, whose opinions are always worthy of attention, it is one of the greatest defects of the laws of England (and we may fay the fame thing of the laws of Scotland), that "they are not provided with any other punishment than that of death, sufficiently terrible to keep offenders in awe. Transportation, which is the punishment second in the order of severity, answers the purpose of example very imperfectly; not only because exile is in reality a flight punishment to those who have neither property, nor friends, nor regular means of fubfistence at home, but because the punishment, whatever it be, is unobserved and unknown. A transported convict may suffer under his sentence, but his sufferings are removed from the view of his countrymen; his mifery is unfeen; his condition strikes no terror into the minds of those for whose warning and admonition it was intended. This chasm in the scale of punishment produces also two farther imperfections in the administration of penal justice; of which the first is, that the fame punishment is extended to crimes of very different characters and malignancy; and the fecond, that punishments, separated by a great interval, are assigned to crimes hardly diftinguishable in their guilt and mischief."

Perhaps this chasm might be properly filled up by houses of correction under judicious management, which might likewise promote another important purpose, better than the punishments in common use.

The end of punishment is twofold, amendment and example. In the first of these, the reformation of crimi-

nals, little has ever been effected, and little indeed feems Corre practicable by the punishments known to the laws of Britain. From every species of punishment inflicted among us, from imprisonment and exile, from pain and infamy, malefactors return more hardened in their crimes, and more instructed. The case we think would often be different when they returned to the world from a well-regulated house of correction. As experience is the only fafe guide in matters of legislation and police. we shall lay before our readers M. Thouin's account of the house of correction at Amsterdam, which seems to corroborate our opinion.

The Amsterdam correction house, from the employ. ment of the prisoners confined in it, is called the raspinghouse, and is destined to the reception of those malefac. tors whose crimes do not amount to a capital offence. Their punishment cannot so properly be denominated folitary confinement as a fequestration from fociety during a limited term of years. The building is fituated in a part of the fuburbs to the north east of the city. The exterior has nothing remarkable, either with respect to form or extent. It is detached from the ffreet by a spacious court, which contains the keeper's lodge, together with apartments for the different fervants belonging to the establishment. Over the gate, which opens from this court into the prison, are placed two statues, as large as life, representing two men in the act of fawing a piece of logwood.

The inner court is in the form of a square, round which are arranged the apartments of the prisoners, together with the necessary warehouses. One part of the ground flory is divided into different chambers; the other ferves as a depot for the logwood, and the imple-

ments employed in its preparation.

The keeper, whose countenance, contrary to the general custom of persons of his profession, was strongly indicative of urbanity and gentleness, introduced M. Thouin into an apartment where two prisoners were at work in fawing a large log of Campeachy wood. The faw is composed of four blades joined together, with very strong, large, and sharp teeth, which make a sciffure in the wood of nearly two inches in breadth. The operation is repeated, till the pieces become too small to undergo the faw, when they are ground in mills peculiarly constructed for this purpose.

This employment requires an extraordinary exertion of strength, and is at first a severe penance even to robust persons; but habit, address, and practice, soon render it easy; and the prisoners in a short time become competent to furnish, without painful exertion, their weekly contingent of 200 lb. weight of fawed pieces. After completing this task, they even find time to fa-bricate a variety of little articles in wood and straw, which they fell to those who visit the prison, or dispose

of, by means of agents, in the town.

M. Thouin next inspected three apartments of different dimensions, which opened into the inner court. The one was inhabited by four, the fecond by fix, and the third by ten prisoners. The furniture of the rooms confisted in hammocks, with a matrass, a blanket, and a coverlid to each, tables, chairs, and stools, glass, &c. earthen veffels, and various other articles of convenience. Every thing in these apartments was distinguished by neatness and propriety; and notwithstanding the number of inhabitants allotted to each, was fully adequate to the dimensions of the rooms; the senses were not offended with any difagreeable fcent, and the air was in every respect as pure and wholesome as the surrounding atmosphere.

In an obscure part of the building are a number of cells, in which formerly those prisoners who revolted against the proper subordination of the place, or illtreated their comrades, were confined for a few days. But the keeper affured M. Thouin that these cells had not been made use of for upwards of 10 years. They are dark gloomy dungeons, with only a small aperture for the admission of light and air. The suppression of this barbarous and coercive punishment does honour to the humanity of government:

The store-rooms are filled with various kinds of wood for the purposes of dyeing; as the haemotoxylum campechianum, the morus tinctoria, the caesalpinia sappan, &c. They are all exotics, with the exception of the Evonymus Europæus. The warehouses were not of fufficient extent to contain the quantity of wood, which was deposited in piles in different parts of the court.

The prisoners, amounting to 76 in number, were uniformly habited in coarse woollens; wear very good flockings, large leather shoes, white shirts, and caps or hats. They are, by the rules of the house, obliged to frequent ablutions, which greatly contribute to the pre-fervation of their health. There was only one fick per-fon amongst them; and, what is not a little remark. able, almost all the prisoners had formerly lived in large commercial towns; very few villagers were amongst them. They had all been sentenced to imprisonment for theft; but it depends upon themselves, by reformation and good behaviour, to shorten the term of their confinement, which many of them frequently do.

The keeper, whose humanity to the unfortunate perfons committed to his care intitles him rather to the title of their protector than their gaoler (and M. Thouin informs us, that the prisoners generally called him by no other name than father), affifts them with his counfels and friendly admonitions. He registers every week, in a book appropriated to this purpose, both the inflances of good and bad behaviour, which is annually fubmitted to the examination of the magistracy, who, from this report, abridge or prolong the term of confinement, according to the degree of indulgence which each prisoner appears to merit. Cases frequently happen where a malefactor, condemned to an imprisonment of eight years, by his good behaviour procures his enlargement at the expiration of four; and fo in proportion for a shorter term. But great attention is paid to discriminate between actual reform and hypocritical

The reward of good behaviour is not, however, confined to, or withheld till, the period of actual liberation. Their refloration to fociety is preceded by a progref-five amelioration of their lot. Their work is gradually rendered less laborious, they are accommodated with separate apartments, and employed in the fervices of domestic economy. The keeper even entrusts them with

commissions beyond the precincts of the prison; and Correction. scarce a fingle instance has occurred of their abusing this indulgence. By this prudent management, a considerable saving is effected in the expence of the establishment, at the same time that it tends to wear away prejudice, and to initiate the prisoners by gradual advances into the reciprocal duties of focial life.

M. Thouin made particular inquiries whether it was customary for persons after their discharge to be confined a fecond and third time, as is but too often the case in many countries, for a repetition of their offence. He was informed, that fuch instances very rarely occur; but the case is not without precedent, as he observed in the person of a young Jew, who was then in the rasp-ing house for the third time. The case of this man is somewhat extraordinary. During the period of his detention, he always conforms, with the most scrupulous observance, to the rules of the place, and gives general satisfaction by his exemplary conduct. But such, as he himself avowed to our traveller, is his constitutional propenfity to thieving, that no fooner is the term of his imprisonment elapsed, than he returns with redoubled ardour to his lawlefs courses. It is not fo much for the fake of plunder, as to gratify his irrififtible impulse, that he follows this vicious life; and M. Thouin adds, that he recounted his different exploits with as much exultation and triumph as a veteran displays when rehearfing his warlike atchievements.

Another falutary regulation in this institution, from which the best consequences result, is the indulgence granted to the prisoners of receiving the vifits of their wives and mistresses twice every week. Proper care, however, is taken to guard against the introduction of disease; and the ladies, in one sense, purchase their admission by giving a trifling sum of money at the gate, which becomes the perquifite of the aged prifoners, whose wants are of a different nature from their youthful comrades. Thus the pleasures of one class contribute to the comforts of the other; and the entrance money, trifling as it is, keeps away a croud of idle vagabonds, who have no acquaintance with the prisoners. The ladies at their visits are permitted to eat and drink with their lovers; and when the conversation becomes too animated for a third person to be present, the rest of the company obligingly take the hint, and leave them to enjoy a tete-a-tete. - By this prudent regulation, many hurtful consequences attendant on a total seclusion from

female lociety are guarded against. M. Thouin concludes his account with observing, that the rasping-house at Amsterdam bears a greater refemblance to a well-ordered manufactory than to a prifon. It were to be wished, that all similar institutions were conducted upon a fimilar plan (A).

So fays our author: But though we have admitted experience to be the only fafe guide in regulating inftitutions of this kind, we cannot help thinking that the plan is susceptible of improvement. We do not see the propriety of locking up four, fix, or ten thieves in the fame apartment. The uncommon attention to cleanli-

⁽A) We do not know that M. Thouin's journal of his travels has been yet published. Extracts from it have been inserted into the Decade, a periodical publication at Paris, whence this account of the Amsterdam house of correction was first copied into the Monthly Magazine for June 1798.

may indeed prevent the room from having an offensive fcent; but what can prevent fuch a number of unprincipled persons from corrupting each other in Holland, as we know that they do in Great Britain? The introduction of females of loofe character to felons fuffering punishment for their offences in a prison, is a practice which we trust will be approved only by philosophers of the French school. The British philosopher, whom we have already quoted with approbation, is of opinion, and we heartily agree with him, that " of reforming punishments, none promises so much success as that of folitary imprisonment, or the confinement of criminals in separate apartments. This improvement of the Amsterdam house of correction would augment the terror of the punishment, would feelude the criminal from the fociety of his fellow-prisoners, in which fociety the worse are sure to corrupt the better; would wean him from the knowledge of his companions, and from the love of that turbulent pernicious life in which his vices had engaged him; would raife up in him reflections on the folly of his choice, and dispose his mind to fuch bitter and continued penitence, as might produce a lasting alteration in the principles of his conduct."

In some houses of correction, the prisoners are subjected to the discipline of flagellation at stated intervals. We will not take it upon us to fay that this punishment is never proper; but we are fully convinced that it is not often fo; and that flagellation, if it can at all produce any good effect, must be administered in private. It is observed by Fielding, who well understood human nature, that fasting is the proper punishment of profligacy, not any punishment that, like flagellation, is attended with shame. Punishment (fays he) that deprives a man of all fense of honour, never will contribute to make him virtuous; and we believe it is generally admitted by the gentlemen of the army, that a foldier who has fuffered the punishment of whipping feldom proves good for any thing.

COURTESEY OF SCOTLAND. See LAW (Encycl.),

Part III. sect. ix. § 28.

COWRY-SHELLS, the lowest money in some parts of the East. See Money (Encycl.), where they are lass. called karis.

CRANE, in mechanics, a machine used for raising or lowering great weights. For the principles on which these machines act, see Dynamics in this Supplement, and likewise Mechanics, Encycl. where descriptions

are given of feveral very powerful cranes.

The crane in common use is employed with some danger to those who work it; and therefore a machine of this kind, acting upon a fimple and certain principle, by which the men walking in the wheel can lower goods with fafety as well as expedition, has long been confidered as a great defideratum in mechanics. Repeated premiums have been offered by the Society for the Encouragement of Arts to induce ingenious men to attempt the invention of fuch a machine; and various have been the contrivances for accomplishing so desirable a purpose. A clergyman, who subscribes E. C. we suppose as the initials of his name, proposes, through the medium of the Repertory of Arts, to accomplish it merely by introducing the action of a worm or fcrew into the crane.

Whenever a worm of two threads is introduced into

Correction nels, which diftinguishes all ranks among the Dutch, a machine, all retrograde motion is stopped, unless that Cran worm receive its reaction from the first moving force; for, powerfully as a worm acts upon a wheel, a wheel has no power upon a worm, whatever force may be applied to it. Suppose, then, the first motion in a crane were given by a worm upon the axis of the wheel in which the man walks, the man would have perfect command of the macline, to raise or lower the goods at pleafure, with the remotest possibility of being overpowered by the descending weight.

"Were I to construct (fays the author) a crane upon this principle, I would have the axis of the wheel in which the man walks, and the axis of the worm, in feparate parts, and occasionally united by a coupling box. When goods were to be raifed, the two axes should be connected; when lowered, they might be difunited, and the worm turned by a winch, which would be done much more expeditiously that way than by the wheel. For the reasons before suggested, the descent of the weight could be accelerated or stopped at pleasure, at

the diferetion of the person turning the winch. "This contrivance might be not inconveniently applied to a crane already erected upon the common principle: Let there be a wheel put upon any convenient axis in the machine as it now flands; upon this let there lie a worm, that can be thrown in or out of gear at pleasure; and let the lever by which it is done he within reach of the man's hand in the wheel. 'The goods being fastened to the crane, and raised off the floor of the warehouse ready for letting down, the man puts the worm into gear, leaves the wheel, and lets the goods down by the winch. Provided it can be conveniently done, it would be advisable to throw the wheel in which the man walks out of gear when the winch is made use of; this, however, I should apprehend, would not be a matter of absolute necessity."

Our author is aware of two objections which may be urged against the introduction of a worm into a crane in the manner which he proposes. The first arises from the flowness of the motion produced by the turning of a screw, which he considers as unworthy of regard; because the necessary speed is to be gained by the first pair of wheels and the diameter of the barrel of the wind-

To the fecond, arifing from the supposed greater friction between a worm and wheel, he replies, that as the friction between the teeth of two wheels (if not formed on the true epicycloidal principle) must, while it lasts, be greater than between a worm and wheel for the fame space of time, it feems no unreasonable suppofition that the aggregate of friction will, in the two cases, nearly balance each other; especially if it be taken into the account, that to obtain the power of one worm and wheel, there will be, in most cases, required two pair of wheels, and two additional axes-all which will add to the friction. But, granting the balance of friction to be against the action of the worm, the power to overcome it is greater in proportion than to overcome the friction of two wheels.

Mr James Whyte of Chevening, in the county of Kent, whose improvement in the construction of pullies, has, with due respect, been noticed elsewhere *, gives, * See ! in the Transactions of the Society for the Encouragement chanics, of Arts, &c. the following description of a new crane 27. Ent.

for wharfs:

A (fig. 1.), a circular inclined plane, moving on a pivot underneath it, and carrying round with it the axis E. A person walking on this plane, and pressing against the lever B, throws off the gripe D, by means of an iron rod C; and thus admits the plane and its axis to move freely, and raise the weight G by the coil-

ing of the rope F round the axis E.

To shew more clearly the construction and action of the lever and gripe, a plan of the circular inclined planc, with the lever and gripe, is added (fee fig. 2.), where B represents the lever, D the spring or gripe. In this plan, when the lever B is in the fituation in which it now appears, the fpring or gripe D presses against the periphery of the plane, as shewn by the double line, and the machine cannot move; but when the lever B is pressed out to the dotted line H, the gripe is also thrown off to the dotted line I, and the whole machine left at liberty to move. One end of a rope or cord, of a proper length, is fixed near the end of the lever B, and the other end made fast to one of the uprights, ferving to prevent the lever moving too far when prefled by the man.

The properties of this crane, for which the premium of 40 guineas was adjudged by the fociety to the in-

ventor, are as follows:

1. It is simple, confisting merely of a wheel and axle. 2. It has comparatively little friction, as is obvious from the bare inspection of the figure. 3. It is durable, as is evident from the two properties above mentioned. 4. It is fafe ; for it cannot move but during the pleafurc of the man, and while he is actually preffing on the gripe-lever. 5. This crane admits of an almost infinite variety of different powers, and this variation is obtained without the least alteration of any part of the machine. If, in unloading a vessel, there should be found goods of every weight, from a few hundreds to a ton and upwards, the man that does the work will be able so to adapt his strength to each as to raise it in a space of time proportionate to its weight; he walking always with the same velocity as nature and his greatest

cafe may teach him.

It is a great disadvantage in some cranes, that they take as long time to raise the smallest as the largest weight, unless the man who works them turn or walk with fuch velocity as must foon tire him. In other cranes, perhaps, two or three different powers may be procured; to obtain which, some pinion must be shifted, or fresh handle applied or resorted to. In this crane, on the contrary, if the labourer find his load fo heavy as to permit him to ascend the wheel without its turning, let him only move a step or two toward the circumference, and he will be fully equal to the task. Again, if the load be so light as scarcely to resist the action of his feet, and thus to oblige him to run through fo much space as to tire him beyond necessity, let him move laterally towards the centre, and he will foon feel the place where his strength will suffer the least satigue by raifing the load in question. One man's weight applied to the extremity of the wheel would raife upwards of a ton; and it need not be added, that a finglefheaved block would double that power. Suffice it to fay, that the fize may be varied in any required ratio; and that this wheel will give as great advantage at any point of its plane as a common walking-wheel of equal diameter, as the inclination can be varied at pleasure,

as far as expediency may require. It may be necessary to observe, that what in the figure is the frame, and feems to form a part of the crane, must be considered as a part of the house in which it is placed; since it would be mostly unnecessary should such cranes be erected in houses already built. With respect to the horizontal part, by walking on which the man who attends the gib occasionally affists in raising the load, it is not an effential part of this invention, where the crane is not immediately contiguous to the gib, although, where it is, it would be certainly very convenient and econo-

CRANE is also a popular name for a syphon, employ-

ed in drawing off liquors.

CROSS, in furveying, is an instrument confisting of a brass circle, divided into four equal parts by two lines croffing each other in the centre. At each extremity of these lines is fixed a perpendicular sight, with small-holes below each slit, for the better discovering of distant objects. The cross is mounted on a staff or stand, to fix it in the ground, and is very useful for measuring small pieces of land, and taking offsets, &c.

Cross-flaff, or Fore-flaff, is a mathematical instrument of box or pear-tree, confishing of a square staff of about three feet long, having each of its faces divided like a line of tangents, and having four cross pieces of unequal lengths to fit on the staff, the halves of these being as the radii to the tangent lines on the faces of the staff .- The instrument was used in taking the altitudes

of the celestial bodies at sea.

CROWN, in astronomy, a name given to two con-stellations, the fouthern and the northern.

Crown, in geometry, a plane ring included between two parallel or concentric peripheries of unequal circles.

CROWN-Post, is a post in some buildings standing up. right in the middle between two principle rafters; and from which proceed struts or braces to the middle of each rafter. It is otherwise called a king post, or king's.

piece, or joggle-piece.

LA CRUZ, an excellent harbour on the north-west coast of America, discovered by the Spaniards in 1779. They were introduced into it by a passage which they called Bucarelli's entrance, and which they placed in 55° 18' N. Lat. and 139° 15' W. Long. from the meridian of Paris. There is no good reason to question the exactuess of the latitude of this passage as laid down by the Spaniards; but the editor of Perouse's voyage justly concludes, from the furvey made by our celebrated navigator Captain Cook on the coasts adjacent to the entrance of Bucarelli, that this entrance is about 135° 20' to the west of Paris, or very nearly 133° west of Greenwich.

The Spaniards were not long in the harbour of La Cruz before they received a vifit from the inhabitants in its neighbourhood. Bartering took place. The Indians gave their peltry, and various trifles, for glass beads, bits of old iron, &c. By this traffic the Spaniards were enabled to gain a fufficiently exact knowledge of their genius, of their offensive and defensive

arms, of their manufactures, &c.

Their colour is a clear olive; many among them have, however, a perfectly white skin: their countenance is well proportioned in all its parts. They are robust, courageous, arrogant, and warlike.

They clothe themselves in one or two undressed skins (with

not change position with so much agility as if they were less burdened.

Their offensive arms are arrows; bows, of which the strings are woven like the large cords of our best musical instruments; lances, four yards in length, tongued with iron; knives, of the fame metal, longer than European bayonets, a weapon however not very common among them; little axes of flint, or of a green stone, so hard that they cleave the most compact wood without injury to their edge.

The pronunciation of their language is extremely difficult; they speak from the throat, with a movement of the tongue against the palate. The little use the women make of the inferior lip greatly injures the diffinctiveness of their language. The Spaniards could neither pronounce nor write the words which they heard.

From the vivacity of spirit in these Indians, and from their attention amply to furnish the market established in the harbour, it may be concluded that they are pretty laborious. They continually brought stuffs well woven and shaded by various colours, the skins of land and fea wolves, of otters, bears, and other smaller animals; of these some were raw, and others dressed. There were to be found at this market also coverlets of coarfe cloth, fhaded with white and brown colours, very well woven, but in small quantities: large ribbons of the same linen which might match with that of the Spanish officers mattreffes; skeins of thread such as this cloth was made of; wooden plates or bowls neatly worked; fmall boats, or canoes, painted in various colours, the figures of which represented heads with all their parts; frogs in wood, nicely imitated, which opened like tobacco boxes, and which they employed to keep their trinkets in: boxes made of small planks, of a cubical form, being three quarters of a yard on each fide, with figures well drawn, or carved on the outfide, representing various animals; the covers fabricated like Flanders etwees, with rabbeted edges, formed fo as to thut into the body of the box; animals in wood, as well those of the earth as of the air; figures of men of the same material, with skull-caps representing the heads of various fierce animals; fnares and nets for fifthing; copper collars for the neck, and bracelets of iron for the wrist, but which they would not part with except at a very high price; beak-like instruments, from which they drew founds as from a German flute. The principal officers took fuch of these merchandizes as were most agreeable to them, and left the remainder to the fhips crews.

As the Indians discovered that the Spaniards were very dainty in their fish, they did not let them want for choice: the greatest abundance was in falmon, and a fpecies of fole or turbot three yards and a quarter long, broad and thick in proportion; cod and pilchards were also brought to market, and fishes refembling trout. From all this it may be inferred, that this gulf is full of fish; the banks too are covered with shells.

The quantity of mother-of-pearl that these Indians cut to pieces for making ear-rings awakened the curiofity of the Spaniards: they tried to discover whether these people had not in their possession, or whether their country did not produce pearls, or fome precious stones: their refearches were fruitless, they only found some stones which they judged to be metallic, and which they

CYMZ. (with the fur apparently); these are the skins of otters, the arrows of their enemies; but thus armed, they canof sea wolves, of benades (a species of deer), of bears, or other animals, which they take in hunting. Thefe dreffes cover them from the neck to the middle of the leg; there are, however, many among them who wear boots of fmooth skin, resembling English boots, only that those of the Indians open before, and are laced tight with a string. They wear hats woven from the fine bark of trees, the form of which refembles that of a funnel or a cone. At the wrifts they have bracelets of copper or iron, or for want of these metals the fins of whales; and round the neck, necklaces of small fragments of bones of fishes and other animals, and even copper collars of the bigness of two singers. They wear in their ears pendants of mother of pearl, or flat pieces of copper, on which is emboffed a refin of a topaz colour, and which are accompanied with jet beads. Their hair is long and thick, and they make use of a comb to hold it together in a small queue from the middle to the extremity; a narrow ribbon of coarse linen, woven for this purpose, serves as a ligament. They wear also as a covering a kind of scarf, woven in a particular manner, fomething more than a yard and a half long, and about half a yard broad, round which hangs a fringe fomething more than half a quarter of a yard

deep, of which the thread is regularly twifted. The women give proofs of their modesty and decency by their dress. Their physiognomy is agreeable, their colour fresh, their cheeks vermilioned, and their hair long; they plait it together in one long trefs. They wear a long robe of a smooth skin tied round the loins, like that of a nun; it covers them from the neck as low as the feet; the fleeves reach down to the wrifts. Upon this robe they put divers skins of otters or other animals to defend themselves from the inclemency of the weather. Better dreffed, many of them might difpute charms with the most handsome Spanish women; but distatisfied with their natural charms, they have recourse to art, not to embellish, but to disfigure themfelves. All the married women have a large opening in the under lip, and this opening or orifice is filled up by a piece of wood cut in an oval shape, of which the smallest diameter is almost an inch; the more a woman is advanced in years the more this curious ornament is extended: it renders them frightful, the old women efpecially, whose lip, deprived of its wonted spring, and dragged by the weight of this extraordinary jewel, necessarily hangs in a very disagreeable manner. The girls wear only a copper needle, which croffes the lip in the place where the ornament is intended hereafter to be

placed.

These Indians in war make use of cuirasses and shoulder pieces of a manufacture like that of the whalebone stays among the Europeans. Narrow boards or scantlings form, in some fort, the woof of the texture, and threads are the warp: in this manner the whole is very flexible, and leaves a free use to the arms for the handling of weapons. They wear round the neck a coarfe and large gorget which covers them as high as below the eyes, and their head is defended by a morion, or skull piece, usually made of the head of some ferocious animal. From the waist downwards, they wear a kind of apron, of the same contexture as their cuirass. Lastly, a fine skin bangs from their shoulders down to the knee. With this armour, they are invulnerable to

Fig. 2.

carried on board, not having the necessary means for ex-

tracting the metal they might contain.

These Indians feed upon fish, fresh or dry, boiled or roafted; herbs and roots which their mountains yielded them, and particularly that which in Spain is called fea parsley; and, lastly, upon the slesh of animals which they take in hunting: the productions of the chase are undoubtedly abundant, feeing the number of dogs they

keep for this purpose.

These Indians appeared to the Spaniards to worship the fun, the earliest and most natural of all idolatrous workip; and they paid a decent respect to the remains of their dead. Don Maurelle, one of the Spanish officers, in an expedition round the gulf, found in twoislands three dead bodies laid in boxes of a similar form to those which have been described above, though considerably larger, and deeked in their furs. Thefe biers were placed in a little hut upon a platform, or raifed floor, made of the branches of trees.

The country is very hilly, the mountains are lofty, and their flope extends almost every where to the sea. The foil, lime-stone; it is nevertheless covered with an impenetrable forest of tall fir trees, very large and very strait. As these trees cannot strike very deep into the earth, the violence of the wind often tears them up by the roots: they rot and become a light mould, upon which grows a bushy thicket; and in this are found nettles, camomile, wild celery, anife, a species of cabbage, celandine, elder, wormwood, forrel; and without doubt there are other plants along the rivers.

The Spaniards faw ducks, gulls, divers, kites, ravens, geele, storks, gold-finches, and other little birds un-

known to them.

The commerce between the Spaniards and the Indians was quite undifturbed; and fo defirous were the latter to obtain iron, cloth, and other stuffs, that they fold their children for broken iron hoops and other The Spaniards in this manner bought three young lads, one from five to fix years old, another of four, and the third from nine to ten, not to make flaves, but Christians of them; they hoped besides to derive useful information from them as to the nature of the country and its inhabitants. These youths were fo contented in being with the Spaniards, that they hid themselves when their parents came on board, from the apprehension of being again restored to them. Two young girls were also purchased with the same view; one very ugly, seven years of age; the other younger, better made, but fickly, and almost at the gates of death.

At the full and change of the moon, the fea rifes in the harbour of La Cruz seventeen feet three inches English; it is then high water at a quarter after 12 at noon: the lowest tides are sourteen feet three inches; the night tides exceed by one foot nine inches those of the day.

conic sections.

CULLEN (Dr William) was a man to whom phyfical science is so deeply indebted, that it has often struck us with wonder that no account of him has yet been given to the public, which deserves to be classed with British biography. We know indeed that a life of him has been written by an eminent physician well qualified and strongly inclined to do justice to the merits of his revered preceptor; but that life has been withheld from us by him who has certainly the best right to consider himself as the guardian of the Doctor's fame, and who, we have been told, is to enlarge and publish it himself. In this state of things our readers must pardon us for laying before them a very imperfect account of this emineut man, to whom we were ourselves almost strangers. There is a character of him in the periodical publication called The Bee, which we shall appropriate to our own use, we are persuaded, with the entire approbation of its author, though fometimes we may express our suspicions that his praise is exag-

Dr William Cullen was born in Lanarkshire, in the west of Scotland, 11th December 1712. His father was for some time chief magistrate of the town of Hamilton; but though a very respectable man, his circumstances were not such as to permit him to lay out much money on the education of his fon. William therefore, after ferving an apprenticeship to a surgeon apothecary in Glasgow, went several voyages to the West Indies as a furgeon in a trading veffel from London: but of this employment he tired, and fettled himself, at an early period of life, as a country furgeon in the parish of Shotts, where he staid a short time practising among the farmers and country people, and then went to Hamilton with a view to practife as a physician, having never been fond of operating as a furgeon.

While he resided near Shotts, it chanced that Archibald Duke of Argyle, who at that time bore the chief political sway in Scotland, made a visit to a gentleman of rank in that neighbourhood. The Duke was fond of literary pursuits, and was then particularly engaged in some chemical researches, which required to be elucidated by experiment. Eager in these pursuits, his Grace, while on this vifit, found himself much at a loss for the want of fome fmall chemical apparatus, which his landlord could not furnish: but happily recollecting young Cullen in the neighbourhood, he mentioned him to the Duke as a person who could probably furnish it. -He was accordingly invited to dine; was introduced to his Grace,-who was fo much pleafed with his knowledge, his politeness and address, that he formed an acquaintance which laid the foundation of all Doctor Cullen's future advancement.

The name of Cullen by this time became familiar at every table in that neighbourhood; and thus he came to be known, by character, to the Duke of Hamilton. who then refided, for a fhort time, in that part of the country: and that nobleman having been fuddenly taken ill, the affittance of young Cullen was called in.;

Cullen. which proved a fortunate circumstance in ferving to afterwards filled with so much honour to himself and sa- Cullen. promote his advancement to a station in life more suited to his talents than that in which he had hitherto moved.

The character of the Douglasses, of which name the family of Hamilton now forms a principal branch, has always been fomewhat of the same stamp with that of the rifing Cullen. Genius, benevolence, frankness, and conviviality of disposition, have been, with them in general, very prominent features: and if to that be added a spirit of fiolic and dissipation, these will be accounted as only natural consequences of those youthful indulgences that spring from an excess of wealth at an early period of life, and the licence allowed to people of elevated rank. The Duke was therefore highly delighted with the sprightly character and ingenious conversation of his new acquaintance. Receiving instruction from him in a much more pleafing, and an infinitely easter way than he had ever before obtained, the conversation of Cullen proved highly interesting to his Grace-No wonder then that he foon found means to get his favourite Doctor, who was already the efteemed acquaintance of the man through whose hands all preferments in Scotland were obliged to pass, appointed to a place in the university of Glasgow, where his singular talents for discharging the duties of the station he now occupied foon became very conspicuous (A).

During his refidence in the country, however, feveral important incidents occurred, that ought not to be passed over in filence. It was during this time that was formed a connection in business in a very humble line between two men, who became afterwards eminently conspicuous in much more exalted stations. William, afterwards Doctor, Hunter, the famous lecturer on anatomy in London, was a native of the same part of the country; and not being in affluent circumstances more than Cullen, these two young men, stimulated by the impulse of genius to prosecute their medical studies with ardour, but thwarted by the narrowness of their fortune, entered into a copartnery bufiness as surgeons and apothecaries in the country. The chief end of their contract being to furnish the parties with the means of profecuting their medical studies, which they could not separately so well enjoy, it was stipulated, that one of them alternately should be allowed to study in what college he inclined, during the winter, while the other should carry on the business in the country for their common advantage. In consequence of this agreement, Cullen was first allowed to study in the Univerfity of Edinburgh for one winter; but when it came to Hunter's turn next winter, he, preferring London to Edinburgh, went thither. There his fingular neatness in diffecting, and uncommon dexterity in mathen read lectures upon anatomy and midwifery there; fed; fo that his fame continued to increase. who engaged Hunter as an affiftant, and whose chair he

tisfaction to the public.

Thus was diffolved, in a premature manner, a copartnery perhaps of as fingular a kind as is to be found in the annals of literature: nor was Cullen a man of that disposition to let any engagement with him prove a bar to his partner's advancement in life. The articles were freely departed from by him; and Cullen and Hunter ever after kept up a very cordial and friendly correspondence; though, it is believed, they never from that time had a personal interview.

During the time that Cullen practifed as a country furgeon and apothecary, he formed another connection of a more permanent kind, which, happily for him, was not dissolved till a very late period of his life. With the ardour of disposition he possessed, it cannot be supposed he beheld the fair sex with indifference. Very early in life he took a strong attachment to an amiable woman, a Miss Johnston, daughter to a clergyman in that neighbourhood, nearly of his own age, who was prevailed on to join with him in the facred bonds of wedlock, at a time when he had nothing elfe to recommend him to her except his person and dispositions; for as to riches and possessions he had little of these to boast of. She was beautiful, had great good fense, equanimity of temper, an amiable disposition, and elegance of manners, and brought with her a little money, which, though it would be accounted nothing now, was fomething in those days to one in his situation in life. After giving to him a numerous family, and participating with him the changes of fortune which he experienced, the peacefully departed this life in fummer 1786.

In the year 1746, Cullen, who had now taken the degree of doctor in phylic, was appointed a lecturer in chemistry in the University of Glasgow: and in the month of October began his lectures in that science. His fingular talents for arrangement, his distinctness of enunciation, his vivacity of manner, and his knowledge of the science he taught, rendered his lectures interesting to the students to a degree that had been till then unknown at that university. He became, therefore, in fome measure, adored by the students. The former professors were eclipsed by the brilliancy of his reputation; and he had to experience all those little rubs that envy and disappointed ambition naturally threw in his way. Regardless, however, of these secret shagreens, he presfed forward with ardour in his literary career; and, supported by the favour of the public, he consoled himfelf for the contumely he met with from a few individuals. His practice as a physician increased from day to day; and a vacancy having occurred in the year 1751, he was then appointed by the king professor of king anatomical preparations, his affiduity in study, his medicine in that university. This new appointment mildness of manner, and pliability of temper, soon re- ferved only to call forth his powers, and to bring to commended him to the notice of Dr Douglas, who light talents that it was not formerly known he posses-

As, at that period, the patrons of the university of Edinburgh

⁽A) It was not, however, folely to the favour of these two great men that Cullen owed his literary fame. He was recommended to the notice of men of science in a way still more honourable to himself. The disease of the Duke of Hamilton having refifted the effect of the first applications, Dr Clarke was sent for from Edinburgh; and he was so much pleased with every thing that Cullen had done, that he became his eulogist upon every occasion. Cullen never forgot this; and when Clarke died, gave a public oration in his praise in the University of Edinburgh; which, it is believed, was the first of the kind in this country.

ullen. Edinburgh were constantly on the watch for the most eminent medical men to support the riling fame of the college, their attention was foon directed towards Cullen; who, on the death of Dr Plumber, professor of chemistry, was, in 1756, unanimously invited to accept the vacant chair. This invitation he accepted: and having refigned all his employments in Glasgow, he began his academical career in Edinburgh in the month of October of that year; and there he resided till his

If the admission of Cullen into the university of Glasgow gave great spirit to the exertions of the students, this was still, if possible, more strongly felt in Edinburgh. Chemistry, which had been till that time of finall account in that univerfity, and was attended to by very few of the students, instantly became a favourite Audy; and the lectures upon that science were more frequented than any others in the university, anatomy alone excepted. The fludents, in general, spoke of Cullen with the rapturous ardour that is natural to youth when they are highly pleased. These eulogiums appeared extravagant to moderate men, and could not fail to prove disgusting to his colleagues. A party was formed among the students for opposing this new favourite of the public; and these students, by misreprefenting the doctrines of Cullen to others who could not have an opportunity of hearing these doctrines themfelves, made even some of the most intelligent men in the university think it their duty publicly to oppose these imaginary tenets. The ferment was thus augmented; and it was some time before the professors discovered the arts by which they had been imposed upon, and univerfal harmony restored.

During this time of public ferment, Cullen went fleadily forward, without taking any part himfelf in these disputes. He never gave ear to any tales respecting his colleagues, nor took any notice of the doctrines they taught: That some of their unguarded strictures might at times come to his knowledge, is not impossible; but if they did, they feemed to make no impression

These attempts of a party of students to lower the character of Cullen on his first outset in the university of Edinburgh having proved fruitless, his fame as a protesfor, and his reputation as a physician, became more and more respected every day. Nor could it well be otherwise: Cullen's professional knowledge was always great, and his manner of lecturing fingularly clear and intelligible, lively and entertaining; and to his patients, his conduct in general as a physician was so pleasing, his address so affable and engaging, and his manner so open, fo kind, and fo little regulated by pecuniary confiderations, that it was impossible for those who had occasion to call once for his medical affistance, ever to be satisfied on any future occasion without it. He became the friend and companion of every family he vifited; and his future acquaintance could not be dispensed with.

But if Dr Cullen in his public capacity deferved to be admired, in his private capacity by his students he deferved to be adored. His conduct to them was so attentive, and the interest he took in the private concerns of all those students who applied to him for advice, was so cordial and so warm, that it was impossible for any one who had a heart susceptible of generous emotions, not to be enraptured with a conduct fo uncommon and

SUPPL. VOL. I. Part II.

fo kind. Among ingenuous youth, gratitude eafily Cullen. degenerates into rapture—into respect nearly allied to adoration. Those who advert to this natural construction of the human mind, will be at no lofs to account for that popularity that Cullen enjoyed-a popularity, that those who attempt to weigh every occurrence by the cool flandard of reason alone, will be inclined to think excessive. It is fortunate, however, that the bulk of mankind will ever be influenced in their judgment not less by feelings and affections than by the cold and phlegmatic dictates of reason. The adoration which generous conduct excites, is the reward which nature hath appropriated exclusively to difinterested beneficence. This was the secret charm that Cullen ever carried about with him, which fascinated fuch numbers of those who had intimate access to him. This was the power which his envious opponents never

could have an opportunity of feeling.

The general conduct of Cullen to his students was thus. With all fuch as he observed to be attentive and diligent, he formed an early acquaintance, by inviting them by twos, by threes, or by fours at a time, to sup with him, converfing with them on these occasions with the most engaging ease, and freely entering with them on the subject of their studies, their amusements, their difficulties, their hopes, and future prospects. In this way, he usually invited the whole of his numerous class. till he made himself acquainted with their abilities, their private character, and their objects of pursuit. Those among them whom he found most assiduous, best disposed, or the most friendless, he invited the most frequently, till an intimacy was gradually formed, which proved highly beneficial to them. Their doubts, with regard to their objects of study, he listened to with attention, and folved with the most obliging condescenfion. His library, which confifted of an excellent affortment of the best books, especially on medical subjects, was at all times open for their accommodation; and his advice, in every case of difficulty to them, they always had it in their power most readily to obtain. They feemed to be his family; and few persons of distinguished merit have left the university of Edinburgh in his time, with whom he did not keep up a correfpondence till they were fairly established in business. By these means, he came to have a most accurate knowledge of the state of every country, with respect to practitioners in the medical line; the only use he made of which knowledge, was to direct students in their choice of places, where they might have an opportunity of engaging in bufiness with a reasonable prospect of Many, very many, able men has he thus put into a good line of bufiness where they never could have thought of it themselves; and they are now reaping the fruits of this beneficent forefight on his part.

Nor was it in this way only that he befriended the fludents at the university of Edinburgh. Possessing a benevolence of mind that made him ever think first of the wants of others, and recollecting the difficulties that he himself had had to struggle with in his younger days, he was at all times fingularly attentive to their pecuniary concerns. From his general acquaintance among the students, and the friendly habits he was on with many of them, he found no difficulty in discovering those among them who were rather in hampered circumstances, without being obliged to hurt their de-

3 N

habits of fludy admitted of it, he was peculiarly at-They were more frequently invited to his house than others; they were treated with more than usual kindness and familiarity; they were conducted to his library, and encouraged by the most delicate address to borrow from it freely whatever books he thought they had occasion for: and as persons in these circumstances were usually more shy in this respect than others, books were fometimes pressed upon them as a fort of constraint, by the Doctor infilling to have their opinion of fuch or fucli paffages they had not read, and defiring them to carry the book home for that purpose. He, in short, behaved to them rather as if he courted their company, and stood in need of their acquaintance than they of his. He thus raifed them in the opinion of their acquaintance to a much higher degree of estimation than they could otherwise have obtained; which, to people whose minds were depressed by penury, and whose sense of honour was sharpened by the consciousness of an inferiority of a certain kind, was singularly engaging. Thus they were inspired with a fecret sense of dignity, which elevated their minds, and excited an uncommon ardour of pursuit, instead of that melancholy inactivity which is so natural in such circumstances, and which too often leads to despair. Nor was he less delicate in the manner of fupplying their wants, than attentive to discover them. He often found out some polite excuse for refusing to take payment for a first course, and never was at a loss for one to an after course. Before they could have an opportunity of applying for a ticket, he would fometimes lead the conversation to fome subject that occurred in the course of his lectures; and as his lectures were never put in writing by himfelf, he would sometimes beg the favour to see their notes, if he knew they had been taken with attention, under a pretext of affilting his memory. Sometimes he would express a wish to have their opinion of a particu. lar part of his course, and presented them with a ticket for that purpose; and sometimes he refused to take payment, under the pretext that they had not received his full course the preceding year, some part of it having been necessarily omitted for want of time, which he meant to include in this course. By such delicate address, in which he greatly excelled, he took care to forcrun their wants. Thus he not only gave them the forcrun their wants. Thus he not only gave them the benefit of his own lectures, but by refusing to take their money, he also enabled them to attend those of others that were necessary to complete their course of fludies. These were particular devices he adopted to individuals to whom economy was necessary; but it was a general rule with him, never to take money from any fludent for more than two courses of the same set of lectures, permitting him to attend these lectures as many years longer as he pleafed gratis.

He introduced another general rule into the univerfity, that was dictated by the same principle of difinterested beneficence, that ought not to be here passed over in silence. Before he came to Edinburgh, it was the custom of medical professors to accept of sees for their medical affistance, when wanted, even from medical students themselves, who were perhaps attending the professor's own lectures at the time. But Cullen never would take fees as a physician from any student at the university, though he attended them, when

licacy in any degree. To fuch perfors, when their called in as a physician, with the same affiduity and Collen, care as if they had been persons of the first rank, who paid him most liberally. This gradually induced others to adopt a fimilar practice; so that it is now become a general rule for medical professors to decline taking any fees when their assistance is necessary to a student. For this useful reform, with many others, the fludents of the univerfity of Edinburgh are folely indebted to the liberality of Dr Cullen.

The first lectures which Cullen delivered in Edinburgh were on chemistry; and for many years he also gave clinical lectures on the cases which occurred in the royal infirmary. In the month of February 1763, Dr Alfton died, after having begun his usual course of lectures on the materia medica; and the magistrates of Edinburgh, as patrons of that professorship in the univerfity, appointed Dr Cullen to that chair, requesting that he would finish the course of lectures that had been begun for that feason. This he agreed to do; and though he was under a necessity of going on with the course in a few days after he was nominated, he did not once think of reading the lectures of his predeceffor, but resolved to deliver a new course entirely his own. The popularity of Cullen at this time may be gueffed at by the increase of new students who came to attend his courle in addition to the eight or ten who had entered to Dr Alfton. The new students exceeded 100. An imperfect copy of these lectures thus fabricated in haste, having been published, the Doctor thought it necessary to give a more correct edition of them in the latter part of his life. But his faculties being then much impaired, his friends looked in vain for those striking beauties that characterifed his literary exertions in

the prime of life. Some years afterwards, on the death of Dr White, the magistrates once more appointed Dr Cullen to give lectures on the theory of phylic in his flead. And it

was on that occasion Dr Cullen thought it expedient to retign the chemical chair in favour of Dr Black, his former pupil, whose talents in that department of science were then well known, and who has filled the chair ever fince with great fatisfaction to the public. Soon after, on the death of Dr Rutherford, who for many years had given lectures with applause on the practice of phyfic, Dr John Gregory (whose name can never be mentioned by any one who had the pleasure of his acquaintance without the warmest tribute of a grateful respect) having become a candidate for this place along with Dr Cullen, a fort of compromife took place between them, by which they agreed each to give lectures alternately on the theory and on the practice of physic during their joint lives, the longest furvivor being allowed to hold either of the classes he should incline. In consequence of this agreement, Dr Cullen delivered the first course of lectures on the practice of physic in winter 1766, and Dr Gregory succeeded him in that branch the following year. Never perhaps did a literary arrangement take place that could have proved more beneficial to the students than this. Both these men posfeffed great talents, though of a kind extremely diffimilar. Both of them had certain failings or defects, which the other was aware of, and counteracted. Each of them knew and respected the talents of the other. 'They co-operated, therefore, in the happiest manner, to enlarge the understanding, and to forward the pursuits of

their pupils. Unfortunately this arrangement was foon destroyed by the unexpected death of Dr Gregory, who was cut off in the flower of life by a fudden and unforeseen event. After this time, Cullen continued to give lectures on the practice of physic till a sew months before his death, which happened on the 5th of February 1790, in the 77th year of his age.

In drawing the character of Dr Cullen, Dr Anderfon, to whom we are indebted for this sketch, observes, that in scientific pursuits men may be arranged into two grand classes, which, though greatly different from each other in their extremes, yet approximate at times fo near as to be blended indifcriminately together; those who possess a talent for detail, and those who are endowed with the faculty of arrangement. The first may be faid to view objects individually as through a microscope. The field of vision is confined; but the objects included within that field, which must usually be confidered fingly and apart from all others, are feen with a wondrous degree of accuracy and distinctness. The other takes a sweeping view of the universe at large, considers every object he perceives, not individually, but as a part of one harmonious whole: His mind is therefore not fo much employed in examining the feparate parts of this individual object, as in tracing its relations, connections, and dependencies, on those around it. - Such was the turn of Cullen's mind. The talent for arrangement was that which peculiarly diftinguished him from the ordinary class of mortals; and this talent he possessed perhaps in a more distinguished degree than any other person of the age in which he lived. Many persons exceeded him in the minute know? ledge of particular departments, who, knowing this, naturally looked upon him as their inferior; but poffessing not at the same time that glorious faculty, which, "with an eye wide roaming, glances from the earth to heaven," or the charms which this talent can infuse into congenial minds, felt difgust at the pre-eminence he obtained, and aftonishment at the means by which he obtained it. An Aristotle and a Bacon have had their talents in like manner appretiated; and many are the persons who can neither be exalted to sublime ideas with Homer, nor ravished with the natural touches of a Shakespeare. Such things are wisely ordered, that every department in the universe may be properly filled by those who have talents exactly suited to the talk assigned them by heaven.

-Had Cullen, however, possessed the talents for arrangement alone, small would have been his title to that high degree of applause he has attained. Without a knowledge of facts, a talent for arrangement produces nothing but chimeras; without materials to work upon, the structures which an over-heated imagination may rear up are merely "the baseless fabric of a vision." No man was more sensible of the justness of this remark than Dr Cullen, and few were at greater pains to avoid it. His whole life, indeed, was employed, almost without interruption, in collecting facts. Whether he was reading, or walking, or converfing, these were continually falling into his way. With the keen perception of an eagle, he marked them at the first glance; and without stopping at the time to examine them, they were ftored up in his memory, to be drawn forth as occasion required, to be confronted with other facts that had been obtained after the same manner, and to have their truth afcertained, or their falfity proved, by the evidence Cullen. which should appear when carefully examined at the impartial bar of justice. Without a memory retentive in a fingular degree, this could not have been done; but so very extraordinary was Dr Cullen's memory, that till towards the very decline of life, there was fearcely a fact that had ever occurred to him which he could not readily recollect, with all its concomitant circum?ances, whenever he had occasion to refer to it. It was this faculty which fo much abridged his labour in fludy, and enabled him so happily to avail himself of the labour of others in all his literary speculations. He often reaped more by the conversation of an hour than another man would have done in whole weeks of labo-

rious fludy.

In his prelections, Dr Cullen never attempted to read. His lectures were delivered viva voce, without having been previously put into writing, or thrown into any particular arrangement. The vigour of his mind was fuch, that nothing more was necessary than a few flort notes before him, merely to prevent him from varying from the general order he had been accustomed to observe. This gave to his discourses an ease, a vivacity, a variety, and a force, that are rarely to be met with in academical discourses. His lectures, by consequence, upon the same subject were never exactly the fame. Their general tenor indeed was not much varied; but the particular illustrations were always new, well fuited to the circumstances that attracted the general attention of the day, and were delivered in the particular way that accorded with the cast of mind the prelector found himself in at the time. To these circumstances must be ascribed that energetic artless elocution, which rendered his lectures fo generally captivating to his hearers. Even those who could not follow him in those extensive views his penetrating mind glanced at, or who were not able to understand those apt allusions to collateral objects which he could only rapidly point at as he went along, could not help being warmed in some measure by the vivacity of his manner. But to those who could follow him in his rapid career, the ideas he fuggested were so numerous, the views he laid open were to extensive, and the objects to be attained were so important—that every active faculty of the mind was rouled; and fuch an ardour of enthulialm was excited in the profecution of study, as appeared to be perfectly inexplicable to those who were merely unconcerned spectators. In consequence of this unshackled freedom in the composition and delivery of his lectures, every circumstance was in the nicest unison with the tone of voice and expression of countenance, which the particular cast of mind he was in at the time inspired. Was he joyous, all the figures introduced for illustration were fitted to excite hilarity and good humour: was he grave, the objects brought under view were of a nature more folemn and grand: and was he pecvish, there was a peculiarity of manner in thought, in word, and in action, which produced a most striking and interesting effect. The languor of a nervelets uniformity was never experienced, nor did an abortive attempt to excite emotions that the speaker himself could not at the time feel, ever produce those discordant ideas which prove difgufting and unpleating.

It would feem as if Dr Cullen had confidered the

proper bufinels of a preceptor to be that of putting his

Cullen. pupils into a proper train of fludy, so as to enable them to profecute those studies at a future period, and to carry them on much farther than the short time allowed for academical prelections would admit. He did not, therefore, fo much strive to make those who attended his lectures deeply verfed in the particular details of objects, as to give them a general view of the whole fubject; to shew what had been already attained respecting it; to point out what remained yet to be difcovered; and to put them into a train of fludy that should enable them, at a future period, to remove those difficulties that had hitherto obstructed our progress; and thus to advance of themselves to farther and farther degrees of perfection. If these were his views, nothing could be more happily adapted to them than the mode he invariably purfued. He first drew, with the striking touches of a master, a rapid and general outline of the subject, by which the whole figure was seen at once to start boldly from the canvas, diffinct in all its parts, and unmixed with any other object. He then began anew to retrace the picture, to touch up the leffer parts, and to finish the whole in as perfect a manner as the state of our knowledge at the time would permit. Where materials were wanting, the picture there continued to remain imperfect. The wants were thus rendered obvious; and the means of supplying these were pointed out with the most careful discinination. The student, whenever he looked back to the subject, perceived the defects; and his hopes being awakened, he felt an irref:stible impulse to explore that hitherto untrodden path which had been pointed out to him, and fill up the chasm which still remained. Thus were the active faculties of the mind most powerfully excited; and instead of labouring himself to supply deficiencies that far exceeded the power of any one man to accomplish, he set thousands at work to fulfil the task, and put them into a train of going on with it, when he himfelf should be gone to that country "from whose dread bourne no traveller returns."

It was to these talents, and to this mode of applying them, that Dr Cullen owed his celebrity as a professor; and it was in this manner that he has perhaps done more towards the advancement of science than any other man of his time, though many individuals might perhaps be found who were more deeply verfed in the particular departments he taught than he himself was. Chemistry, which was before his time a most disgusting purfuit, was by him rendered a fludy fo plcafing, fo eafy, and so attractive, that it is now profecuted by numbers as an agreeable recreation, who but for the lights that were thrown upon it by Cullen and his pupils, would never have thought of engaging in it at all; though perhaps they never heard of Cullen's name, nor have at this time the most distant idea that they owe any obligations to him; and the same may be said of the other branches of science which he taught.

According to a man who knew him well, there are three things which eminently distinguished Cullen as a professor. "The energy of his mind, by which he viewed every subject with ardour, and combined it immediately with the whole of his knowledge.

"The scientific arrangement which he gave to his Subject, by which there was a lucidus ordo to the dullest scholar. He was the first person in this country who made chemistry cease to be a chaos.

"A wonderful art of interesting the fludents in every Curle thing which he taught, and of raising an emulative enthufiafm among them."

We are well aware that this character will by many be deemed an extravagant panegyric; but having no opportunity of judging for ourselves, we would rather adopt from others an extravagant panegyric than an unmerited censure. Dr Anderson himself admits that Cullen's character was far from perfect; and, in the opinion of most other men with whom we have converfed on the subject, and who were at the same time qualified to form an estimate of his mental powers, his imagination was not balanced by his judgment. Hence the common remark in the university of Edinburgh, that Dr Cullen was more fuccessful in demolishing the theories of others than in giving stability to those which were reared by himfelf.

Dr Cullen's external appearance, though striking and not unpleafing, was not elegant. His countenance was expressive, and his eye in particular remarkably lively, and at times wonderfully penetrating. In his person he was tall and thin, flooping very much about the fhoul-When he walked, he had a contemplative look, and did not feem much to regard the objects around him.

CURFEU-BELL (see Curfew, Encycl.), called in the law Latin of the middle ages ignitegium or pyritegium, and in French, cuvre-feu-was a fignal for all persons to extinguish their fires at a certain hour. In those ages people made fires in their houses in a hole or pit in the centre of the floor, under an opening formed in the roof; and when the fire was burnt out, or the family went to bed, the hole was flut by a cover of wood or of earth. This practice still prevails among the cottagers in some parts of Scotland, and we doubt not of other countries. In the dark ages, when all ranks of people were turbulent, a law was almost everywhere established, that the fire should be extinguished at a certain time in the evening; that the cover should be put over the fire-place; and that all the family should retire to rest, or at least keep within doors. The time when this ought to be done was fignified by the ringing of a bell, called therefore the curfeu-bell or ignitegium. The law of William the Conqueror, which introduced this practice into England, as has been mentioned in the Encyclopædia, was abolished by Henry I. in 1100.

The ringing of the curfeu-bell gave rife to the prayer-bell, as it is ealled, which is still retained in some Protestant countries. Pope John XXIII. with a view to avert certain apprehended misfortunes, which rendered his life uncomfortable, gave orders, that every person, on hearing the ignitegium, should repeat the Ave Maria three times. When the appearance of a comet, and a dread of the Turks, afterwards alarmed all Chriftendom, Pope Calixtus III. increased these periodical times of prayer, by ordering the prayer-bell to be rung also at noon. Beckmann's History of Inventions.

CURVE OF EQUABLE APPROACH. It was first proposed by Leibnitz, namely, to find a curve, down which a body descending by the force of gravity shall make equal approaches to the horizon in equal portions of time. It has been found by Bernoulli and others, that the curve is the fecond cubical parabola, placed with its vertex uppermost, and which the descending body must enter with a certain determinate velocity. Varignon rendered the question general for any law of gravity, gravity, by which a body may approach towards a given point by equal fpaces in equal times. And Maupertuis also resolved the problem in the case of a body descending in a medium which results as the square of

the velocity.

CUSSO, or BANKSIA ABYSSINICA, is a beautiful and useful tree, indigenous to the high country of Abyssinia. At least Mr Bruce, who has given of it the only description which we have seen, says, that he never saw it in any other part of Asia or Africa. It seldom grows above twenty feet high, very rarely straight, generally crooked or inclined. Its least, which is of a deep unvarnished green, having the fore part covered with soft hair or down, is about 2½ inches long, divided by a strong rib into two unequal divisions, of which the upper is broader and larger than the lower. It is more indented than even the nettle least, which it in some measure resembles, only the least of the Cusso is narrower and longer.

Those leaves grow two and two upon a branch, having between each two the rudiments of two pair of leaves, which probably are deciduous; but the branch is terminated with a fingle leaf or flipula at the point. The end of this stalk is broad and strong, like that of a palm branch. It is not folid like the gerid of the date tree, but opens in the part that is without leaves about an inch and a half from the bottom, and out of this aperture proceeds the flower. There is a round stalk, bare for about an inch and a quarter, from which proceed crooked branches with fingle flowers attached to their ends; the stalk that carries these proceeds out of every crook or geniculation. The whole cluster of flowers has very much the shape of a cluster of grapes; the stalks which support it resemble the stalks of the grape; and a very few small leaves are scattered through

the clufter of flowers.

"The calyx or flower cup is of a greenish colour, tinged with purple; when fully blown it is altogether of a deep red or purple; the corolla is white, and confits of five petals; in the midst is a short pittil with a round head, surrounded by eight stamina, of the same form, loaded with yellow farina. The cup confits of five petals, which much resemble another slower; they are rounded at the top, and nearly of an equal breadth every way. 'The seed is very small, smaller than even

the femen fantonicum; and being likewise very bitter it is used in Abyssinia as a vermisuge. From its smallness, however, and its being very easily shed, no great quantity of it is ever gathered, and therefore the flower is often substituted in its stead. The Abyssinians, says our author, of both sexes, and at all ages, are troubled with the fort of worm called ascarides, of which every individual evacuates a large quantity once a-month. The method of promoting these evacuations is by infusing a handful of dry cusso flowers in about two English quarts of bouza, or the beer they make of test (see Teff Encycl.), and after it has been steeped all night, the next morning it is fit for use.

"The bark of the tree is smooth, of a yellowish white, interspersed with brown streaks, which pass through the whole body of the tree It is not firm or hard, but rather stringy and reedy. On the upper part, before the first branch of leaves set out, are rings round the trunk, of small slaments of the consistence of horse hair: these are generally sourteen or sixteen in number, and are a very remarkable characteristic belonging to the tree."

From this description, which, it must be confessed, is not remarkable for perspicuity, and from an inspection of the figure which Mr Bruce has given of the cusso, we are inclined to rank it with the palms, as a

new genus, nearest to the caryota.

CUVETTE, or CUNETTE, in fortification, is a kind of ditch within a ditch, being a pretty deep trench, about four fathoms broad, funk and running along the middle of the great dry ditch, to hold water; ferving both to keep off the enemy and prevent him from mining.

CYCLE of Indiction, is a feries of 15 years, returning conftantly around like the other cycles, and commenced from the third year before Christ; whence it happens that if 3 be added to any given year of Christ, and the sum be divided by 15, what remains is the year

of the indiction.

CYCLOID (fee Encycl.) is a curve, which is thus generated: Suppose a wheel or circle to roll along a straight line till it has completed just one revolution; a nail or point in that part of the circumference of the circle, which at the beginning of the motion touches the straight line, will, at the end of the revolution, have described on a vertical plane a cycloid.

And the second s

Part of the second seco

DAGELET, the name given by La Perouse, the celebrated though unfortunate navigator, to an island on the coast of Corea (see Corea Encycl.), which he discovered in the year 1787. It is little more than three leagues in circumference; and our author almost made its circuit at the distance of a mile without finding bottom. This small spot is very steep, but covered with

the finest trees from the sea shore to the summit. A rampart of bare rock, like a wall, encircles the whole outline of it, with the exception of seven little sandy creeks, where it is possible to land. In these creeks the Frenchmen saw upon the stocks some boats of a construction altogether Chinese; but the sight of their ships frightened the workmen, who sted from their

fifty paces diltant. As a few huts were feen, but neither villages nor cultivation, La Perouse concluded that the island is without inhabitants, and that the men whom he faw at work were Corean carpenters, who during the fummer months go with provision to Dagelet for the purpose of building boats, which they sell upon the continent. He places the north east point of this island in N. Lat. 37°. 25'. and E. Long. 129°. 2'. from

DAIRY is a word which fignifies fometimes the art of making various kinds of food from milk; fometimes the place where milk is manufactured; and fometimes the management of a milk farm. On the dairy, in the first and second of these senses, enough has been said in the Encyclopadia under the titles BUTTER, CHEESE, and DAIRY; on the management of a milk-farm that

work contains nothing.

When a dairy is established, the undertaker may fometimes think it his interest to obtain the greatest possible quantity of produce; sometimes it may be more beneficial for him to have it of the finest quality; and at other times it may be necessary to have both these objects in view, the one or the other in a greater or less proportion; it is therefore of importance that he should know how he may accomplish the one or the other of these purposes in the easiest and most direct manner.

To be able to convert his milk to the highest possible profit in every cafe, he ought to be fully acquainted with every circumstance respecting the manufacture both of butter and of cheese; as it may in some cases happen, that a certain portion of that milk may be more advantageously converted into butter than into cheefe, while another portion of it would return more

profit if made into cheefe.

The first thing to be adverted to, in an undertaking of this nature, is to choose cows of a proper fort. Among this class of animals, it is found by experience, that some kinds give milk of a much thicker consistence, and richer quality, than others; nor is this richness of quality necessarily connected with the smallness of the quantity yielded by cows of nearly an equal fize; it therefore behoves the owner of a dairy to be peculiarly attentive to this circumstance. In judging of the value of a cow, it ought rather to be the quantity and the quality of the cream produced from the milk of the cow, in a given time, than the quantity of the milk itfelf: this is a circumstance that will be shewn hereafter to be of more importance than is generally imagined. The small cows of the Alderney breed afford the richeft milk hitherto known; but individual cows in every country may be found, by a careful felection, that afford much thicker milk than others; these therefore ought to be searched for with care, and their breed reared with attention, as being peculiarly valuable.

Few persons, who have had any experience at all in

dock-yard into the wood, which was not more than the dairy, can be ignorant, however, that in comparing the milk of two cows, to judge of their respective qualities, particular attention must be paid to the time that has elapsed fince their calving; for the milk of the same cow is always thinner foon after calving than it is afterwards; as it gradually becomes thicker, though generally less in quantity, in proportion to the time tince the cow has calved. The colour of the milk, soon after calving, is richer than it is afterwards; but this, especially for the first two weeks, is a faulty colour, that ought not to be coveted.

To make the cows give abundance of milk, and of a good quality, they must at all times have plenty of food. Grass is the best food yet known for this purpose, and that kind of grass which springs up spontaneoully on rich dry foils is the best of all. If the temperature of the climate be such as to permit the cows to graze at ease throughout the day, they should be fuffered to range on fuch pastures at freedom; but if the cows are io much incommoded by the heat as to be prevented from eating through the day, they ought in that case to be taken into cool shades for protection; where, after allowing them a proper time to ruminate, they thould be supplied with abundance of green food, fresh cut for the purpose, and given to them by hand frequently, in small quantities, fresh and fresh, so as to induce them to eat it with pleasure. When the heat of the day is over, and they can remain abroad with eafe, they may be again turned into the pasture, where they should be allowed to range with freedom all night, during the mild weather of fummer.

Cows, if abundantly fed, should be milked three times a-day, during the whole of the fummer feafon (A); in. the morning early, at noon, and in the evening, just before night-fall. In the choice of persons for milking the cows, great caution should be employed; for it that operation be not carefully and properly performed, not only the quantity of the produce of the dairy will be greatly diminished, but its quality also will be very much debased; for if all the milk be not thoroughly drawn from a cow when the is milked, that portion of milk which is left in the udder feems to be gradually absorbed into the system, and Nature generates no more than to supply the waste of what has been taken away. If this lessened quantity be not again thoroughly drawn off, it occasions a yet farther diminution of the quantity of milk generated; and thus it may be made to proceed, in perpetual progression from little to less, till none at all is produced. In short, this is the practice in all cases followed, when it is meant to allow a cow's milk to dry up entirely, without doing her hurt. In this manner, therefore, the profits of a dairy might be wonderfully diminished; so that it much behoves the owner of it to be extremely attentive to this circumstance, if he wishes to avoid ruin. It ought to be a rule without an exception, never to allow this important department

(A) If cows be milked only twice in the day (24 hours), while they have abundance of fucculent food, they will yield a much smaller quantity of milk, in the same time, than if they be milked three times. Some attentive observers think a cow, in these circumstances, will give nearly as much milk at each time, if milked three times, as if she were milked only twice. This fact, however, has not, that we know of, been ascertained by experiment. There can be no doubt but they give more, how much more is not afcertained; nor, whether it would be advantageous, in any cafe, to milk them four times, or oftener; nor, what effect frequent milking produces on the quality of the milk.

department to be entrusted, without controul, to the management of hired fervants (B). Its importance will be still more manifest from what follows.

It is to Dr James Anderson that we are indebted for these judicious observations, as well as for the following aphorifus which, though they may be in part known to attentive housewifes, he has reason to believe are not commonly adverted to as their importance deferves.

"Of the milk that is drawn from any cow at one time, that which comes off at the first is always thinner, and of a much worse quality, than that which comes afterwards; and the richness goes on continually increasing to the very last drop that can be drawn from the udder

orifm

Few persons are ignorant that the milk which is last of all taken from the cow at milking (in this country called froakings) is richer than the rest of the milk; but fewer fill are aware of the greatness of the disproportion between the quality of the first and the last drawn milk, from the same cow, at one milking. following facts (fays our author) respecting this circumflance were afcertained by me many years ago, and have been confirmed by many subsequent experiments and observations.

Having taken feveral large tea-cups, exactly of the same fize and shape, one of these tea cups was filled at the beginning of the milking, and the others at regular intervals, till the last, which was filled with the dregs of the stroakings. These cups were then weighed, the weight of each having been tettled, so as to ascertain that the quantity of milk in each was precifely the fame; and from a great number of experiments, frequently repeated with many different cows, the refult was in all cases as follows:

The quantity of cream obtained from the first drawn cup was, in every case, much smaller than from that which was latt drawn; and those between afforded less or more as they were nearer the beginning or the end. It is unnecessary here to specify these intermediate proportions; but it is proper the reader should be informed, that the quantity of cream obtained from the lastdrawn cup, from fome cows, exceeded that from the first in the proportion of fixteen to one. In other cows, however, and in particular circumstances, the difproportion was not quite fo great; but in no cale did it tall short of the rate of eight to one. Probably, upon an average of a great many cows, it might be found to run as ten or twelve to one.

Secondly, The difference in the quality of the cream, however, obtained from these two cups, was much greater than the difference in the quantity. In the first cup, the cream was a thin tough film, thinner, and perhaps whiter, than writing paper; in the last, the cream was of a thick lutyrous confistence, and of a glowing richnels of colour that no other kind of cream is ever found to possels.

Thirdly, The difference in the quality of the milk

that remained, after the cream was separated, was per- Dairy. haps fill greater than either in respect to the quantity or the quality of the cream. The milk in the first cup was a thin bluish liquid, as if a very large proportion of water had been mixed with ordinary milk; that in the last cup was of a thick confidence, and yellow colour, more refembling cream than milk both in tafte and ap-

From this important experiment, it appears that the person who, by bad milking of his cows, loses but half a pint of his milk, lofes in tact about as much cream as would be afforded by fix or eight pints at the beginning, and lofes, befides, that part of the cream which alone can give richness and high flavour to his butter.

" If milk be put into a difh, and allowed to fland Aphorism till it throws up cream, that portion of cream which rifes first to the surface is richer in quality, and greater in quantity, than what rifes in a fecond equal space of time; and the cream that rifes in the second interval of time is greater in quantity, and richer in quality, than that which rifes in a third equal space of tune; that of the third than the fourth, and fo on: the cream that rifes decreasing in quantity, and declining in quality, continually, as long as any rifes to the furface."

Our ingenious author confesses, that his experiments not having been made with fo much accuracy in this case as in the former, he was not enabled to ascertain the difference in the proportion that takes place in equal portions of time; but they have been fo often repeated as not to leave any room to doubt the fact, and it will be allowed to be a fact of no small importance in the management of the dairy. It is not certain, however, but that a greater quantity of cream may, upon the whole, be obtained from the milk by taking it away at different times; but the process is so troublefome as not to be counterbalanced by the increased quantity obtained, if indeed an increased quantity be thus obtained, which is not as yet quite certain.

" Thick milk always throws up a smaller proportion Aphorism of the cream it actually contains, to the furface, than milk that is thinner; but that cream is of a richer quality. If water be added to that thick milk, it will afford a confiderably greater quantity of cream than it would have done if allowed to remain pure, but its quality is, at the same time, greatly debased."

This is a fact that every person attentive to a dairy must have remarked; but I have never (says our author) heard of any experiment that could afcertain, either the precise amount of the increased quantity of cream that might thus be obtained, or of the ratio in the decrease of its quality. The effects of mixing water with the milk in a dairy are at least ascertained; and the knowledge of this fact will enable attentive persons to follow that practice which they think will best promote their own interest.

"Milk which is put into a bucket or other proper Aphorifus veffel, and carried in it to any confiderable distance, so

(B) Cows should always be treated with great gentleness, and soothed by mild usage, especially when young and ticklish, or when the paps are tender; in which last case, the udder ought to be somented with warm water before milking, and touched with the greatest gentlenese, otherwise the cow will be in danger of contracting bad habits, becoming stubborn and unruly, and retaining her milk ever after. A cow never lets down her milk pleafantly to the person she dreads or dislikes. The udder and paps should always be washed with clean water before milking; but care should be taken that none of that water be admitted into the milking-pail.

put into the milk pans to fettle for cream, never throws up so much, nor so rich cream, as if the same milk had been put into the milk-pans directly after it was milked."

In this case, it is believed the loss of cream will be nearly in proportion to the time that has elapsed, and the agitation the milk has sustained, after being drawn from the cow. But Dr Anderson says that he is not yet in -possession of any experiments which sufficiently ascertain how much is to be ascribed to the time, and the agitation, taken separately. On every branch of agri-culture we find experiments wanting, at each step we advance in our enquiries; and it is the duty of every enquirer to point out, as he goes along, where they are wanted, fince the labours of no one man can poffibly complete the whole.

From the above facts, the following corollaries feem

to be clearly deducible:

First. It is of importance that the cows should be always milked as near the dairy as possible, to prevent the necessity of carrying and cooling the milk before it is put into the dishes; and as cows are much hurt by far driving, it must be a great advantage in a dairyfarm to have the principal grass fields as near the dairy

or homestead as possible.

Secondly. The practice of putting the milk of all the cows of a large dairy into one veffel, as it is milked, there to remain till the whole milking is finished, before any part of it is put into the milk-pans-feems to be highly injudicious; not only on account of the loss that is fulfained by agitation and cooling, but also, more especially, because it prevents the owner of the dairy from distinguishing the good from the bad cow's milk, fo as to separate these from each other, where it is neceffary. He may thus have the whole of his dairy product greatly debased by the milk of one bad cow, for years together, without being able to discover it. A better practice, therefore, would be, to have the milk drawn from each cow put separately into the creamingpans as foon as it is milked, without being ever mixed with any other. Thus would the careful manager of the dairy be able on all occasions to observe the particular quality of each individual cow's milk, as well as its quantity, and to know with precision which of his cows it was his interest to dispose of, and which of them he ought to keep and breed from.

Thirdly. If it be intended to make butter of a very fine quality, it will be advisable in all cases to keep the milk that is first drawn separate from that which comes last; as it is obvious, that if this be not done, the quality of the butter will be greatly debased, without much augmenting its quantity. It is also obvious, that if this is done, the quality of the butter will be improved in proportion to the smallness of the quantity of the lastdrawn milk that is retained; fo that those who wish to

Dairy. as to be much agitated, and in part cooled, before it be be fingularly nice in this respect, will do well to retain Dairy only a very small portion of the last drawn milk.

To those owners of dairies who have profit only in view, it must ever be a matter of trial and calculation, how far it is expedient for them to carry the improving of the quality of their butter at the expence of diminishing its quantity. In different situations prudence will point out different kinds of practice as most eligible; and all persons must be left, after making accurate trials, to determine for themselves. It is likewise a confideration of no small importance, to determine in what way the inferior milk, that is thus to be fet apart where fine butter is wanted, can be employed with the greatest profit. In the Highlands of Scotland they have adopted, without thinking of the improvement of their butter, a very simple and economical practice in this respect. As the rearing of calves is there a principal object with the farmer, every cow is allowed to fuckle her own calf with a part of her milk, the remainder only being employed in the dairy. To give the calf its portion regularly, it is separated from the cow, and kept in an inclosure, with all the other calves belonging to the fame farm. At regular times, the cows are driven to the door of the inclosure, where the young calves fail not to meet them. Each calf is then separately let out, and runs directly to its mother, where it fucks till the dairy-maid judges it has had enough; she then orders it to be driven away, having previously shackled the hinder legs of the mother, by a very simple contrivance, to oblige her to stand still. Boys drive away the calf with switches, and return it to the inclofure, while the dairy-maid milks off what was left by the calf: thus they proceed till the whole of the cows are milked. They obtain only a small quantity of milk, it is true, but that milk is of an exceeding rich quality; which, in the hands of fuch of the inhabitants as know how to manage it, is manufactured into the richest marrowy butter that can be anywhere met with. This richness of the Highland butter is universally ascribed to the old grass the cows feed upon in their remote glens; but it is in fact chiefly to be attributed to the practice here described, which has long prevailed in those regions. Whether a similar practice could be economically adopted elfewhere, our author takes not upon him to fay; but doubtless other secondary uses might be found for the milk of inferior quality. On some occasions, it might be converted into butter of an inferior quality; on other occasions, it might be fold fweet, where the fituation of the farm was within reach of a market-town; and on others, it might be converted into cheefes, which, by being made of fweet milk, would be of a very fine quality if carefully made (c). Still other uses might be devised for its application; of which the following is worthy of notice. Take common skimmed milk, when it has begun to turn four,

(c) The making of cheefe has never yet been reduced to scientific principles, and consequently the reasoning relating to it is very inconclusive. It is in general supposed, that the goodness of cheese depends almost entirely upon its richnels, by which is meant the proportion of oily matter, whether natural or extraneous, it contains; nothing, however, is more certain, than that this opinion is erroncous. Sometimes a very lean cheefe is much better tasted than one that is much fatter; and, which will appear to most persons still more extraordinary, it frequently happens, that a cheese that tastes soft and fat, is much leaner than one that is hard, dry, and slicky. The mode of manufacturing it occasions this, and not the quantity of cream it contains. It is very possible by art to make poor skim milk cheese assume the soft buttery taste and appearance even of cream cheese. This subject, therefore, deserves to be more particularly elucidated than it has hitherto been.

put it into an apright stand-churn, or a barrel with one of its ends out, or any other convenient veffel. Heat fome water, and pour it into a tub that is large enough to contain with eafe the veffel in which the milk was Set the vessel containing the milk into the hot water, and let it remain there for the space of one night. In the morning it will be found that the milk has separated into two parts; a thick cream-like subflance, which occupies the upper part of the veffel, and a thin watery part, that remains at the bottom. Draw off the thin part (called in Scotland wigg) by opening a flop cock, placed for that purpose close above the bottom, and referve the cream for use Not much less than half of the milk is thus converted into a fort of cream, which, when well made, feems to be as rich and fat as real cream itself, and is only diffinguishable from it by its fourness. It is eaten with fugar, and esteemed a great delicacy, and usually fells at double the price of fresh unskimmed milk. It requires practice, however, to be able to make this nicely; the degree of the heat of the water, and many other circumstances, greatly affecting the operation.

Fourthly. If the quality of the butter be the chief object attended to, it will be necessary, not only to separate the first from the last drawn milk, but also to take nothing but the cream that is first separated from the best milk, as it is this first rising cream alone that is of the prime quality. The remainder of the milk, which will be still sweet, may be either employed for the purpose of making sweet milk cheeses, or may be allowed to stand, to throw up cream for making butter of an inferior quality, as circumstances may direct.

Fifthly. From the above facts, we are enabled to perceive, that butter of the very best possible quality can only be obtained from a dairy of confiderable extent, judiciously managed; for when only a small portion of each cow's milk can be fet apart for throwing up cream, and when only a small proportion of that cream can be referved, of the prime quality, it follows (the quantity of milk being upon the whole very inconfiderable), that the quantity of prime cream produced would be fo small as to be scarcely worth manufacturing feparately.

Sinthly. From these premises we are also led to draw another conclusion, extremely different from the opinion that is commonly entertained on this subject, viz. That it feems probable, that the very best butter could be made with economy in those dairies only where the manufacture of cheese is the principal object. The reafons are obvious: If only a fmall portion of milk should be set apart for butter, all the rest may be made into

SUPPL. VOL. I. Part II.

cheefe, while it is yet warm from the cow, and perfect- Dairy, ly fweet; and if only that portion of cream which rifes Dahalac. during the first three or four hours after milking is to be referved for butter, the rich milk which is left after that cream is separated, being still perfectly sweet, may be converted into cheefe with as great advantage nearly as the newly-milked milk itself.

But, as it is not probable that many persons could be found who would be willing to purchase the very finest butter, made in the manner above pointed out, at a price that would be fufficient to indemnify the farmer for his trouble in making it, these hints are thrown out merely to shew the curious in what way butter posselfing this superior degree of excellence may be obtained, if they choose to be at the expence; but for an ordinary market, Dr Anderson is satisfied, from experience and attentive observation, that if in general about the first drawn half of the milk be separated at each milking, and the remainder only fet up for producing cream, and if that milk be allowed to stand to throw up the whole of its cream (even till it begins fenfibly to tafte fourish), and that cream be afterwards carefully managed, the butter thus obtained will be of a quality greatly superior to what can usually be procured at market, and its quantity not confiderably less than if the whole of the milk had been treated alike. This, therefore, is the practice that our author thinks most likely to fuit the frugal farmer, as his butter, though of a superior quality, could be afforded at a price that would always ensure it a rapid sale.

Dr Anderson throws out many other ingenious and useful observations on this important branch of rural economy. In particular, he points out, in the plainest manner, the requisites of a good milk-house, which, as he truly observes, should be cool in summer and warm in winter, so as to preserve a temperature nearly the same throughout the year. But we have treated of this part of the subject elsewhere, and must therefore refer such as are desirous to know the Doctor's sentiments on it, to the Letters and Papers of the Bath and West-of-England Society for the encouragement of agriculture, &c. or to the eighth volume of the Repertory

of Arts and Manufactures.

DAHALAC, the largest island in the Red Sea, is thus described by Mr Bruce. It is low and even, the foil fixed gravel and white fand, mixed with shells and other marine productions. It is deflitute of all forts of herbage, at least in summer, unless a small quantity of bent grass, just sufficient to seed the few antelopes and goats that are on the island. There is a very beautiful fpecies of this last animal found here, small, short-liair-

Connected as they are with the object discussed in the text, we beg leave with our author to suggest the following particulars, as proper objects of examination and experiment, viz. Is the quantity of caseous matter afforded by milk necessarily connected with the proportion of cream that milk contains, or does it depend upon fome other principle not hitherto investigated? Without pretending to decide this question, Dr Anderson feels himself strongly inclined to believe it does not depend upon the quantity of cream. It is well known that cow's milk, which always throws up more cream, and that of a much richer quality, than ewe-milk, does in no cale afford above one half the proportion of cheese that ewe milk does. Nor can this fingular tendency of ewe-milk, to yield a great proportion of curd, be attributed to its superior thickness; for cow-milk can be often had that is thicker and richer than ewe milk, but it always affords a much smaller proportion of curd. From these considerations, it is not impossible but it might be found, upon a careful investigation, that the refuse milk, which ought to be separated from the other in making the best butter, might be equally proper, or very nearly so, for making cheefe, as if no fuch separation had been made. We therefore recommend this as a proper object of experimental enquiry.

Dahalace ed, with thin black sharp horns, having rings upon them, and they are very fwift of foot.

This island is, in many places, covered with large plantations of acacia trees, which grow to no height, feldom above eight feet, but spread wide, and turn flat at top, probably by the influence of the wind from the fea. Though in the neighbourhood of Abyffinia, Dahalac does not partake of its feasons, no rain falls here from the end of March to the beginning of October; but in the intermediate months, especially December, January, and February, there are violent showers for 12 hours at a time, which deluge the island, and fill the cifterns fo as to ferve all next fummer; for there are no hills nor mountains in Dahalac, and confequently no fprings. Thele cifterns alone preserve the water, and of them there yet remain 370, all hewn out of the folid rock. They fay these were the works of the Persians; it is more probable they were those of the first Ptole-But whoever were the constructors of these magnificent refervoirs, they were a very different people from those that now possess them, who have not industry enough to keep one of the 370 clear for the use of man. All of them are open to every fort of animal, and half full of the filth they leave there, after drinking and washing in them; yet one of these cisterns, cleaned and thut up with a door, might afford them wholesome fweet water all the year over.

After the rains fall, a prodigious quantity of grass immediately springs up; and the goats give the inhabitants milk, which in winter is the principal part of their subfistence, for they neither plow nor sow; all their employment is to work the veffels which trade to the different parts of the coast. One half of the inhabitants is constantly on the Arabian side, and by their labour is enabled to furnish with dora (millet or Indian corn) and other provisions the other half who stay at home; and when their time is expired, they are relieved by the other half, and supplied with necessaries in their turn. But the sustenance of the poorer fort is entirely shell and other fish. Their wives and daughters are very bold and expert fisher-women. Several of them, entirely naked, swam off to the vessel before it came to an anchor, begging handfuls of wheat, rice, or do-They are very importunate and sturdy beggars, and not eafily put off with denials. These miserable people, who live in the villages not frequented by barks from Arabia, are fometimes a whole year without tasting bread Yet fuch is the attachment to their place of nativity, they prefer living in this bare, barren, parched spot, almost in want of necessaries of every kind, especially of these effential ones, bread and water, to those pleasant and plentiful countries on both sides of them.

There are in Dahalac twelve villages or towns, of which each has a plantation of doomtrees round it, which furnish the only manufacture in the island. The leaves of this tree, when dried, are of a gloffy white, which might very easily be mistaken for sattin: of these they make baskets of surprising beauty and neatness, flaining part of the leaves with red or black, and working them into figures very artificially. Our author knew some of these, resembling straw-baskets, continue full of water for 24 hours, without one drop coming through. They fell these at Loheia and Jidda, the largest of them for four commesh, or sixpence. This is the employment, or rather amusement, of the men who stay at

home: for they work but very moderately at it, and Dahal all of them indeed take special care not to prejudice their health by any kind of fatigue from industry.

People of the better fort, such as the Shekh and his relations, men privileged to be idle, and never exposed to the fun, are of a brown complexion. But the common fort employed in fishing, and those who go con-flantly to sea, are not indeed black but red, and little

darker than the colour of new mahogany.

The inhabitants of Dahalac seemed to be a simple, fearful, and inoffensive people. It is the only part of Africa or Arabia (call it which you please) where you fee no one carry arms of any kind: neither gnn, knife, nor fword, is to be feen in the hands of any one. Whereas at Loheia, and on all the coast of Arabia, and more particularly at Yambo, every person goes aimed; even the porters, naked and groaning under the weight of their burden and heat of the day, have yet a leather belt, in which they carry a crooked knife, fo monstrously long, that it needs a particular motion and address in walking not to lame the bearer. This was not always the case at Dahalac; several of the Portuguefe, on their first arrival here, were murdered, and the island often treated ill, in revenge, by the armaments of that nation. The men feemed healthy. They told our author they had no difeafes among them, unless fometimes in spring, when the boats of Yemen and Jidda bring the small-pox among them, and very few escape with life that are infected. He did not observe among them a man that feemed to be fixty years old; from which he inferred, that they are not long livers, though the air thould be healthy, as being near the channel, and as they have the north wind all fummer, which moderates the heat.

Dahalac, like all the other islands in the Red Sea, pends upon Masuah. The revenue of its governor depends upon Masuah. confifts in a goat brought to him monthly by each of the twelve villages. Every vessel that puts in there for Mafuah pays him also a pound of coffee, and every one from Arabia a dollar or pataka. No fort of finall money is current at Dahalac, excepting Venetian glassbeads, old and new, of all fizes and colours, broken and whole.

Although this is the miferable state of Dahalac at present, matters were widely different in former times. The pearl fifthery flourished greatly here under the Ptolemies; and even long after, in the time of the caliphs, it produced a great revenue, and till the fovereigns of Cairo, of the prefent miserable race of slaves, began to withdraw themselves from their dependency on the port, Dahalac was the principal island that furnished the pearl fishers or divers. It was, indeed, the chief port for the fishery on the southern part of the Red Sea, as Suakem was on the north; and the basha of Masuah passed part of every fummer here, to avoid the heat at his place of refidence on the continent.

The fishery extended from Dahalac and its islands nearly to lat. 20°. The inhabited islands furnished each a bark and fo many divers, and they were paid in wheat, flour, &c. such a portion to each bark for their use, and fo much to leave with their family for their sublistence; so that a few months employment furnished them with every thing necessary for the rest of the year. The fishery was rented in later times to the basha of Suakem; but there was a place between Suakem and the ac, supposed river Frat, in lat. 21° 28' north, called Gungunnah, which was referved to the grand fignior in particular, and a special officer was appointed to receive the pearls on the fpot and fend them to Constantinople. The pearls found there were of the largest size, and inferior to none in water or roundness. Tradition fays, that this was exclusively the property of the Pharaohs; by which is meant, in Arabian manuscripts, the old

kings of Egypt before Mahomet.

In the same extent, between Dahalac and Suakem, was another very valuable fishery, that of tortoiles, from which the finest shells of that kind were produced, and a great trade was carried on with the East Indies (China especially) at little expence, and with very considerable profits. But the immense treasures in the bottom of the Red Sea have now been abandoned for near 200 years, though they never were richer in all probability than at present. No nation can now turn them to any profit but the English East India Company, more intent on multiplying the number of their enemies, and weakening themselves by spreading their inconsiderable force over new conquests, than creating additional profit by engaging in new articles of commerce. A lettlement upon the river Frat, which never yet has belonged to any one but wandering Arabs, would open them a market both for coarse and fine goods from the southern frontiers of Morocco, to Congo and Angola, and fet the commerce of pearls and tortoife shell on foot again. All this fection of the gulf from Suez, as we are told, is in their charter, and twenty ships might be employed on the Red Sea without any violation of territorial claims. The myrrh, the frankincenfe, some cinnamon, and variety of drugs, are all in the possesfrom of the weak king of Adel; an usurper, tyrant, and Pagan, without protection, and willing to trade with any superior power that only would secure him a miserable livelihood.

There are neither horses, dogs, sheep, cows, nor any fort of quadruped, but goats, affes, a few half-starved camels, and antelopes, at Dahalac, which last are very numerous. The inhabitants have no knowledge of firearms, and there are no dogs nor beafts of prey in the island to kill them; they catch indeed some few of them

in traps.

The language at Dahalac is that of the shepherds, though Arabic, too, is spoken by most of them. Our author states the latitude of Dahalac to lie between 15°

27' 30", and 15° 54' 30" north. DALRYMPLE (Sir David), was born in Edinburgh on the 28th of October (N. S.) 1726. His father was Sir James Dalrymple of Hailes, Bart. and his mother Lady Christian Hamilton, a daughter of the Earl of Hadinton. His grandfather Sir David Dalrymple was the youngest son of the first Lord Stair, and is faid to have been the ablest of that family, so much diffinguished for ability. He was Lord Advocate for Scotland in the reign of George I. and his fon Sir James had the auditorship of the exchequer for

The fubject of this memoir was educated at Eton school, where he was distinguished as a scholar, and long remembered as a virtuous and orderly youth. In that justly celebrated feminary he acquired a classical taste, which, though it was once prevalent in Scotland, has

besides, friendships to persons, and attachments to things, Dalrymwhich accompanied him through life. Hence probably fprung his partiality to English manners and custome, which marked both his public conduct and private converfation, and was the fource of much of his dignity, and fome of his littlenesses.

From Eton he returned to Edinburgh, whence, after the usual course of a gentleman's studies in that univerfity, he went to Utrecht to study the civil law; and remained there till after the rebellion in 1746 Upon his return to his native country, fo promifing were his parts, and fuch his industry and foberness of mind, that very fanguine expectations were entertained of his future eminence; and in some respects these expectations were not frustrated. To his intimate friends it was well known, that if left to follow the bent of his own inclinations, he would have devoted his time and his talents to the study of antiquities and the belles lettres; in both which departments of literature he was eminently qualified to excel. On the death of his father, however, he found his affairs fo very much encumbered. that in order to retrieve them, and to provide for his brothers and fifters, he resolved to follow the law as a profession, in which some of his ancestors had made a dis-

tinguished figure.

He was called to the Scotch bar in 1748, where, notwithstanding the elegant propriety of the cases which he drew, it must be confessed that his success did not answer the expectations which had been formed of him. This was not owing either to want of science or to want of industry, but to certain peculiarities, which, if not inherent in his nature, were the result of early and deep-rooted habits. He possessed on all occasions a sovereign contempt, not only for verbal antithesis, but for well rounded periods, and every thing which had the femblance of declamation; and indeed he was wholly unfitted, by an ill-toned voice and ungraceful elocution, for shining as an orator. No wonder, then, that his pleadings, which were never addressed to the passions, did not rival those of some of his opponents, who, possessed of great rhetorical powers, did not, like him, employ strokes of irony too fine to be perceived by the bulk of any audience, but expressed themselves in full, clear, and harmonious periods. Even his memorials, though claffically written, and often replete with valuable matter, did not on every occasion please the court; for they were always brief, and fometimes, as it was faid, indicated more attention to the minutiæ of forms than to the merits of the cause. Yet on points which touched his own feelings, or the interests of truth and virtue, his language was animated, his arguments forcible, and his fcrupulous regard to form thrown aside.

He was fometimes employed as a depute advocate, which gave him opportunities at the circuits of ditplaying that candour and tenderness of disposition which so well becomes the public profecutor in a criminal court. Of this the following instance may be worth relating. On the first day of the court at Stirling, he was once accosted by another advocate in these words: "Sir David, why is there not a trial this forenoon? I would be getting on." "There are (replied he) some unhappy culprits to be tried for their lives; and therefore it is proper that they have time to confer with their men of law." "That is of little consequence (said the other). in that country been long on the decline; and formed, Last year I came to visit Lord Kames when he was

man accused of a rape. Though I had very little time to prepare, yet I made a decent speech." "Pray, Sir, (faid Sir David), was your client acquitted or condemned ?" "O (replied the other), most unjustly condemned." "That, Sir (faid the depute advocate) is no good argument for hurrying on trials."

To return from this digression, if it be considered as fuch, it is furely to the honour of Sir David Dalrymple, that whatever men thought of his fingularities, his detractors concurred with his admirers in believing him incapable of misleading the judge by a false statement of facts; or his clients, by holding out to them fallacious

grounds of hope.

His high fense of honour, and his inflexible integrity, were indeed univerfally admitted; and it was with the warmest approbation of the public that in 1766 he was appointed one of the judges of the court of fession, the highest civil tribunal in Scotland. He took his feat on the bench, according to the usage of that court, by the title of Lord Hailes, the defignation by which he is generally known among the learned of Europe; and the expectations entertained of him were again fanguine. His unwearied affiduity in lifting dark and intricate matters to the bottom was well known; his elegant and concife manner of expressing his sentiments was admirably fuited to the character of a judge; and his legal opinions had been generally found. Yet it must be confessed, that as a judge he was neither so useful nor so highly revered as he ought to have been from the extent of his knowledge, and his unquestioned integrity. The same minute attention to forms, which had in some degree obstructed his rife at the bar, accompanied him to the bench, and brought upon him the ridicule of the wits about the court (A): and we all know, that the character even of Socrates himself was not able to refift the torrent of ridicule. In extenuation of this foible, it may be observed, that by some of the judges of the court of fession perhaps too little regard has been paid to form; and that forms, even apparently trifling, cannot in legal proceedings be wholly difregarded without involving in danger truth and juftice. Be this as it may, such was the opinion which the other judges entertained of Lord Hailes's accuracy, diligence, and dignified manners, that, in the absence of the prefident, they generally voted him into the vacant

In May 1776 he was appointed one of the lords commissioners of justiciary; and in that station he commanded the respect of all mankind. Fully impressed with a deep fense of the importance of his office, he feemed, in the criminal court, to lay afide his fingularities. So far from throwing his whole weight into the scale of the crown, a charge which has been sometimes brought, we believe unjustly, against the Scotch judges, Lord Hailes, like the judges of England, was always counsel for the prisoner when the king's counsel appeared too strong for their opponents, or when there was any particular intricacy in the cafe. In administering

Dalrym here on the circuit, and he appointed me counsel for a the oath to the witnesses, he had none of that indeco Dalry rum which we have elsewhere centured in some of his brethren (see OATH, Encycl.); but rising solemuly from his feat, he repeated the words in fo ferious a manner, as left no doubt in the most profligate mind but that he was himfelf impressed with a sense of the immediate presence of the Supreme Being, and with the firm belief of a future judgment. When the witness appeared to be young or ignorant, we have beheld, with the utmost love and veneration, the pious pains which his Lordship took to discover whether he was duly acquainted with the nature and obligation of an oath, before he admitted him to fwear; and though it is perhaps impossible for human vigilance and fagacity to prevent perjury altogether in courts of justice, he must furely have been a villain uncommonly hardened and artful who could perjure himself in the presence of Lord Hailes. In doubtful cases his Lordship inclined always to the fide of mercy; but when it became his duty to pais fentence of death upon convicted criminals, he addreffed them in a strain of such piety and commiseration, as to draw tears from the eyes of every beholder, and was calculated to make a deep and proper impresfion on the unhappy person himself. In the discharge of this painful duty, we never faw him furpaffed, and have seldom seen him equalled.

Had Lord Hailes been conspicuous only as a sound' lawyer and an able and upright judge, we should not have thought his life intitled to a place in this Work; but he was no less eminent as a man of general erudition, and as a voluminous author. His skill in classical learning, the belles lettres, and historical antiquities, especially those of his own country, is universally admitted; but it cannot be denied, that the same fastidiousness, and the same microscopic attention to minutiæ, which characterised him as a barrister, prevented him from rifing to that rank in the republic of letters to which his learning and genius would otherwise have infallibly carried him. But if he was not one of the most celebrated writers of the age, he was unquestionably one of the most virtuous; if his publications were not always edifying, they were at least innocent and ingenious; and some of them are in the highest degree valuable. In proof of this affertion, we need instance only his Annals of Scotland, and his Inquiry into the Secondary Causes which Mr Gibbon has assigned for the Rapid Progress of Christianity. Of the former of these works, though little calculated to please the common herd of readers, it may with truth be faid, that in refearch and ingenuity it stands unrivalled among the writings of Scotch antiquaries; and of the latter, it is furely not too much to fay, that it displays uncommon acumen, closeness of reasoning, and zeal for the cause of truth, without the usual rancour of theological controversy.

His taste for retirement, which the state of his affairs rendered for a while necessary, grew upon him as he advanced in years. His conflitution, of which he was very careful, as well as his principles and habits, rendered him averse from diffipation of every kind. After

(A) In a fatirical ballad on the court of fession, Mr Boswell, alluding to Lord Hailes's fondness for verbal criticism, makes him address the president in the following words:

To judge of this matter I cannot pretend, For justice, my Lord, wants an e at the end. m- he was made a judge, he confidered abstraction from the gay and fashionable world as connected with the duty of one whose time was no longer his own; and when he chose to unbend his mind, it was in the fociety of a few easy friends, whom he felected as much for their worth and good humour as for their genius or their learning. He had indeed occasionally much conversation with that constellation of wits and men of science who flourished in Edinburgh at the same period with himself; but it was impossible for friendship or intimacy to subfift between men who thought so differently as he and they thought on the most important of all fubjects. Though an old-fashioned whig, zealously attached to the conflitution, he scorned to take any share in the civil or ecclesiastical broils in which some of his brother judges were warmly engaged for the first 20 years of the present reign; for he looked on these as either frivolous or mischievous.

Although his Lordship's constitution had been long in an enfeebled state, he profecuted his studies, and attended his duty on the bench, till within three days of his death, which happened on the 29th of November.

1792, in the 66th year of his age.

His I ordship was twice married; by his first wife Anne Brown, only daughter of Lord Coalston, one of the udges of the court of fession, he left issue one daughter, who inherits the family estate. His second marriage (of which also there is issue one daughter) was to Helen Fergusson, youngest daughter of Lord Kilkerran, who has the affliction to furvive him. Leaving no male issue, the title of Baronet descends to his nephew.

Though the church of Scotland does not much encourage funeral discourses, a very laudable endeavour was made to render the talents and virtues of Lord Hailes a theme of instruction to mankind, in a sermon preached foon after his death in the church of Invereik, by his learned friend, and venerable pastor, Dr Carlyle; from which we shall transcribe a summary view of his character as a judge, a scholar, a Christian, and a citi-

"His knowledge of the laws was accurate and profound, and he applied it in judgment with the most scrupulous integrity. In his proceedings in the criminal court, the fatisfaction he gave to the public could not be surpassed. His abhorrence of crimes, his tenderness for the criminals, his respect for the laws, and his reverential awe of the Omniscient Judge, inspired him on fome occasions with a commanding sublimity of thought, and a feeling folemnity of expression, that made condemnation feem just as the doom of Providence to the criminals themselves, and raised a falutary horror of crimes in the breaft of the audience.

"Conscious of the dignity and importance of the high office he held, he never departed from the decorum that becomes that reverend character; which indeed it cost him no effort to support, because he acted from principle and fentiment, both public and private. Affectionate to his family and relations, fimple and mild in his manners, pure and conscientious in his morals, enlightened and entertaining in his conversation; he left fociety only to regret, that, devoted as he was to more important employments, he had fo little time to spare for intercourse with them.

"He was well known to be of high rank in the re-

public of letters, and his lofs will be deeply felt through Dalrymmany of her departments. His labours in illustration of the history of his country, and many other works of profound erudition, remain as monuments of his accurate and faithful refearch for materials, and his found judgment in the felection of them. Of his unfeigned piety and devotion, you have very often been witnesses where we now are. I must add, however, that his attendance on religious ordinances was not merely out of respect to the laws and for the fake of example (motives which should never fail to have influence on persons of superior rank, for the most obvious reasons), but from principle and conviction, and the most conscientious regard to his duty; for he not only practifed all the virtues and charities in proof of his faith, but he demonstrated the fincerity of his zeal by the uncommon pains he took to illustrate primitive Christianity, and by his elaborate and able defences of it against its enemies.

"His profound refearches into history, and his thorough knowledge of the laws, made him perfectly acquainted with the progress of the constitution of Britain, from the first dawn of liberty in the common law of the land, and the trial by jury which precede all written records, and afterwards in the origin and establishment of parliaments, through all its viciffitudes and dangers, till at last, by the bleffing of divine Providence, which brought many wonderful events to concur to the fame end, it was renewed, ftrengthened, and finally con-

firmed by the Revolution.

"It was this goodly and venerable fabric of the British constitution which the deceased most respectable character contemplated with admiration and delight (of late, indeed, with a mixture of anxiety and fear), as the temple of piety, as the genuine fource of greater happiness and freedom, to a larger portion of mankind than ever flowed from any government upon earth.

"Ill indeed can the times bear the loss of fuch an affectionate patriot and able guardian of the laws of his country. But we must not mumur at the will of Providence, which in its mercy 'may have withdrawn the good man from the evil to come.' In mercy, I fay, to him, whose righteous spirit was so deeply grieved when ' he faw the wicked rage, and the people imagine a vain thing."

Such is the memorial which, in the hour of recent forrow, followed this excellent man to the grave; and we believe it will yet be allowed to be just by all who had the happiness of his Lordship's acquaintance, and are what he was, friends to the best interests of mankind.

This sketch of the life of Lord Hailes would be more imperfect than even it is, if we could not subjoin to it a catalogue of his publications, of which the greater part are exceedingly curious. We call them publications, because he employed almost as much of his time in republishing old and useful books as in preparing for the press his own valuable works.

Defides his effays in the papers called The World and The Mirror, which are well known and universally admired, his Lordship published the following works:

Sacred Poems, or a Collection of Translations and Paraphrases from the Holy Scriptures; by various authors, Edinburgh, 1751, 12mo. Dedicated to Charles Lord Hope, with a preface of ten pages.

The Wildom of Solomon, Wildom of Jefus the Son, of Sirach, or Ecclesiafticus, 12mo, Edin. 1755.

Dalrym-

Select Discourses (in number nine), by John Smith, late Fellow of Queen's College, Cambridge, 12mo, 291 pages. Edin. 1756; with a preface of five pages, "many quotations from the learned languages translated,—and notes added, containing allusions to ancient mythology, and to the erroneous philosophy which prevailed in the days of the author,—various inaccuracies of flyle have been corrected, and harsh expressions softened."

A Discourse of the unnatural and vile Conspiracy attempted by John Earl of Gowry and his Brother, against his Majesty's person, at St Johnstoun, upon the 5th of Aug. 1600. No date of the republication, but the edition and notes supposed by Lord Hailes, 12mo,

1757

A Sermon, which might have been preached in East Lothian upon the 25th day of October 1761, on Acts xxvii. 1, 2. "The barbarous people shewed us no little kindness." Edin. 1761, pp. 25, 12mo. "Occasioned by the country people pillaging the wreck of two vessels, viz. the Bessy, Cunningham, and the Leith Packet, Pitcairn, from London to Leith, cast away on the shore between Dunbar and North Berwick. All the passengers on board the former, in number 17, perished; sive on board the latter, October 16. 1761."—A most affecting discourse, admirably calculated to convince the offenders!

Memorials and Letters relating to the History of Britain, in the reign of James I. published from the originals, Glasgow, 1762.—Addressed to Philip Yorke, Viscount Royston, pp. 151. "From a collection in the advocate's library, by Balfour of Denmyln." The

preface of four pages, figned Dav. Dalrymple.

The Works of the ever-memorable Mr John Hales of Eaton, now first collected together in 3 vols, Glafgow, 1765; presace of three pages. Dedicated to William (Warburton), Bishop of Gloucester. "The edition said to be undertaken with his approbation; obsolete words altered, with corrections in spelling and punctuation."

A specimen of a book intitled "Ane Compendious Booke of Godly and Spiritual Sangs, collectit out of sundrie parts of the Scripture, with sundrie of other Ballates changed out of prophaine Sanges, for avoyding of Sin and Harlotrie, with augmentation of sundry Gude and Godly Ballates, not contained in the first edition. Edinburgh, printed by Andro Hart," 12mo. Edin. 1765, pp. 42; with a Glossary of sour pages.

Memorials and Letters relating to the History of Britain in the reign of Charles I. published from the originals, Glasgow, 1766, pp. 189. Preface of six pages, signed Dav. Dalrymple, chiefly collected by Mr Wodrow, author of the History of the Church of Scotland. Inscribed to Robert Dundas of Arniston, Lord

Prefident of the Court of Seffion.

An account of the prefervation of Charles II. after the Battle of Worcefter, drawn up by himfelf; to which are added, his Letters to feveral persons. Glafgow, 1766, pp. 190, from the MSS. of Mr Pepys, dictated to him by the king himfelf, and communicated by Dr Sandby, master of Magdalen College. The letters are collected from various books; some of them now first published, communicated by the tutors of the Duke of Hamilton, by the Earl of Dundonald, &c. The presace of sour pages, signed Dav. Dalrymple, dedica-

ted to Thomas Holles, Duke of Newcastle, chancellor Dalru of the university of Cambridge.

The Secret Correspondence between Sir Robert Ce-

cil and James VI. 12mo, 1766.

A Catalogue of the Lords of Seffion, from the Inflitution of the College of Justice in the year 1532, with Historical Notes. Suum cuique—rependet posteritas. Edin. 176-, 4to, pp. 26.

The Private Correspondence of Dr Francis Atterbury, Bishop of Rochester, and his friends, in 1725, never before published. Printed in 1768, 4to. Advertisement, pp. 2. Letters, pp. 10. A fac simile of the first from Bishop Atterbury to John Cameron of Lochiel, to prove their authenticity.

An Examination of some of the Arguments for the High Antiquity of Regiam Majestatem; and an Inquiry into the authenticity of the Leges Malcolmi; by Sir David Dalrymple, 4to, pp. 52. Edin. 1769.

Historical Memoirs concerning the Provincial Councils of the Scottish Clergy, from the earliest Accounts to the Æra of the Reformation; by Sir David Dalrymple. Edinburgh, 1769, 4to, pp. 4t.—Nota, Having no high opinion of the popularity of his writings, he prefixes to this work the following motto. "Si delectamur quum scribimus quis est tam invidus qui ab eo nos abducat? sin laboramus quis est qui alienæ modum statuat industriæ."—Cicero.

Canons of the Church of Scotland, drawn up in the Provincial councils held at Perth, A. D. 1242, and

1269. Edinburgh, 1769, 4to, pp. 48.

Ancient Scottish Poems, published from the MS. of George Bannatyne, 1568. Edin. 1770, 12mo. Preface six pages; Poems pp. 221; very curious notes pp. 92; glossary and lists of passages and words not

understood, pp. 14.

The additional Case of Elizabeth, claiming the title and dignity of Counters of Sutherland; by her Guardians. Wherein the facts and arguments in support of her claim are more fully stated, and the errors in the additional cases for the other claimants are detected, 4to.—This singularly learned and able case was subscribed by Alexander Wedderburn (present Lord Chancellor), and Sir Adam Fergusson, but is the well-known work of Lord Hailes. It ought not to be regarded merely as a law paper of great ability, but as a treatile of prosound research into the history and antiquity of many important and general points of succession and family history. Introduction, pp. 21; the first sour chapters, pp. 70; the first and fixth chapters, pp. 177.

Remarks on the History of Scotland, by Sir David Dalrymple.—" Utinam tam facile vera invenire possem quam falsa convincere." Cicero.—Edin. 1773, inscribed to George Lord Lyttleton, in nine chapters, pp. 284.

Huberti Langueti Epistolæ ad Philippum Sydneium Equitem Anglum, accurante D. Dalrymple de Hailes, Eq. Edinburgh, 1776, 8vo. Inscribed to Lord Chief Baron Smythe.—Virorum Eruditorum Testimonia de Langueto, pp. 7. Epistolæ, pp. 289. Index Nominum, pp. 41.

Annals of Scotland, from the Accession of Malcolm III. furnamed Canmore, to the Accession of Robert I. by Sir David Dalrymple. Edin. 1776, pp. 311. Appendix, pp. 51.

pendix, pp. 51.
Tables of the Succession of the Kings of Scotland,

from Malcolm III. to Robert I. their marriages, children, and time of their death; and also of the Kings of England and France, and of the Popes who were

their contemporaries.

Chronological Abridgement of the Volume, pp. 30. The Appendix contains eight differtations: 1. Of the law of Evenus and Mercheta Mulierum, pp. 17. 2. A commentary on the 22d statute of William the Lion, pp. 8. 3. Of the 18th statute of Alexander III. pp. 5. 4. Bull of Pope Innocent IV. pp. 6. 5. Of Walter Stewart Earl of Menteeth, 1296, pp. 7. 6. Of M'Duff, flain at Falkirk in 1298, pp. 3. 7. Of the death of John Communication of Innocent Iv. pp. 3. 7. Of the death of Iv. Communication of Iv. Communication of Iv. Physics I John Comyn, 10th February, 1305, pp. 4. 8. Of

the origin of the house of Stuart, pp. 6.

Annals of Scotland, from the Accession of Robert I. furnamed Bruce, to the Accession of the House of Stuart; by Sir David Dalrymple, Edin. 1779, 4to, pp. 277. Appendix, pp. 54, containing, 1. Of the manner of the death of Marjory, daughter of Robert 1. pp. 7. 2. Journal of the campaign of Edward III. 13.27. pp. 9. 3. Of the genealogy of the family of Seton in the 14th century. 4. Lift of the Scottish commanders at the battle of Hallidon, 19th July 1383, pp. 11. 5. Whether Edward III. put to death the fon of Sir Alexander Seton, pp. 8. 6. Lift of the Scottish commanders killed or made prisoners at the battle of Durham, pp. 8. 7. Table of kings, p. 1. 8. Corrections and additions to volume i. pp. 16. Chronological abridgement of the volume, pp. 39.

Account of the Martyrs of Smyrna and Lyons, in the 2d century, 12mo, with explanatory notes, Edin. 1776. Dedicated to Bishop Hurd, pp. 68. Notes and illustrations, pp. 142. This is a new and correct verfion of two most ancient epistles, the one from the church at Smyrna to the church at Philadelphia; the other from the Christians at Vienna and Lyons to those in Asia and Phrygia-their antiquity and authenticity are undoubted. Great part of both is extracted from Eufebius's Ecclefiastical History. The former was first completely edited by Archbishop Usher. The author of the notes fays of them, with his usual and fingular modesty, "That they will afford little new or interesting to men of erudition, though they may prove of fome benefit to the unlearned reader." But the erudition he possessed in these branches is so rare, that this notice is innecessary. They display much useful learning and ingenious criticism, and breathe the most ardent zeal, connected with an exemplary knowledge of Christianity. N. B. This is the first volume of the remains of Christian Antiquity.

Remains of Christian Antiquity, with explanatory notes, vol. ii. Edin. 1778, 12mo. Dedicated to Dr Newton bishop of Bristol. Preface, pp. 7. This volume contains the trial of Justin Martyr and his companions, pp. 8. Epiftle of Dionysius bishop of Alexandria, to Fabius bishop of Antioch, pp. 16. The trial and execution of Cyprian bishop of Carthage, pp. The trial and execution of Fructuosus bishop of Tarracona in Spain, and of his two deacons, Augurius and Eulogius, pp. 8. The Maiden of Antioch, pp. 2. These are all newly translated by Lord Hailes from Ruinart, Eusebius, Ambrose, &c. The notes and illustrations of this volume extend from p. 47 to 165, and display a most intimate acquaintance with antiquity, great critical acumen, both in elucidating the fense and

detecting interpolations; and above all, a fervent and Dalrymenlightened zeal, in vindicating fuch fentiments and conduct as are conformable to the word of God, against the malicious farcasms of Mr Gibbon. To this volume is added an appendix of pp. 22. correcting and vindicating certain parts of vol. i

Remains of Christian Antiquity, vol. iii Edin. 1780. Dedicated to Thomas Balguy, D. D. Preface, pp. 2. It contains the History of the martyrs of Palestine in the 3d century, translated from Eusebius, pp. 94. Notes and illustrations, pp 135; in which Mr Gibbon again comes, and more frequently, under review .-The partiality and mifrepresentations of this popular writer are here exposed in the calmest and most satisfactory manner.

Pity it is that Lord Hailes should have printed and published these valuable volumes, and indeed most of his other works, at his own expence; and dispersed them fo liberally to his friends, that they have been

little circulated among any other.

Octavius, a Dialogue, by Marcus Minucius Felix. Edin. 1781, pp. 16. Preface. The speakers are, Cocilius a Heathen, Octavius a Christian; whose arguments prevail with his friend to renounce Paganism and become a Christian proselyte. Notes and illustrations,

Of the manner in which the Perfecutors Died; a Treatise, by L. C. F. Lactantius, Edin. 1782. Infcribed to Dr Porteous bishop of Chester (present bishop of London). Preface, pp. 37. in which it is proved that Lactantius is the author. Text, pp. 125.

Notes and illustrations, pp. 109.
L. C. F. Lactantii Divinarum Institutionum Liber

Quintus seu de Justitia, 1777.

Disquisitions concerning the Antiquity of the Chriflian Church. Glafgow, 1783. Inferibed to Dr Halifax, bishop of Gloucester, pp. 194 .- This small original and most excellent work consists of fix chapters. Chap I. A commentary on the conduct and character of Gallio. Acts xviii. 5, 12, 17. - Chap. 2. Of the time at which the Christian religion became publicly known at Rome.-Chap. 3. Cause of the persecution of the Christians under Nero. In this the hypothesis of Mr Gibbon, vol. i. 4to, p. 641, is examined .-Chap. 4. Of the eminent Heathen writers who are faid (by Gibbon) to have difregarded or contemned Christianity, viz Seneca, Pliny sen. Tacitus, Pliny jun. Galen, Epictetus, Plutarch, Marcus Antoninus. To the admirers of Heathen philosophers, and to those efpecially who state between them and the Christian doctrine any confanguinity, this chapter is earneftly recommended - Chap. 5. Illustration of a conjecture by Gibbon, respecting the silence of Dio Cassius concerning the Christians. In this chapter, with extreme impartiality, he amplifies and supports an idea of Mr Gibbon on this head. Chap. 6. Of the circumstances respecting Christianity that are to be found in the Augustan history.

It feems very probable that the close attention which Lord Hailes appears to have given to fuch subjects, was in some measure the effect of the mistakes and partiality of Gibbon. In no one work from 1776, the date of Mr Gibbon's first publication, has he omitted to trace this unfair and infinuating author; but in 1786 he came forth of fet purpose with the most able and for-

midable

Dalrym- midable reply which he has received, intitled, "An Inquiry into the Secondary Caufes which Mr Gibbon has affigued for the rapid growth of Christianity; by Sir David Dalrymple." Edin. 1786; gratefully and affectionately inscribed to Richard (Hurd) bishop of Worcester, 4to, pp. 213. In five chapters.

Sketch of the Life of John Barclay, 4to, 1786.

Sketch of the Life of John Hamilton, a Secular Priest, 4to (one of the most savage and bigotted adherents of Popery, who lived about A. D. 1600.)

Sketch of the Life of Sir James Ramfay, a general officer in the armies of Gultavus Adolphus king of

Sweden, with a head.

Life of George Leslie (an eminent capuchin friar in the early part of the 17th century), 4to, pp. 24. Sketch of the Life of Mark Alex. Boyd, 4to.

These lives were written and published as a specimen of the manner in which a Biographia Scotica might be executed; and it is likely that Lord Hailes selected

purposely the least interesting.

The Opinions of Sarah Duchefs Dowager of Marlborough, published from her original MSS. 1788, 12mo, pp. 120. (with a few foot notes by Lord Hailes, in which he corrects the splenetic partiality of her

The Address of Q. Sept. Tertullian to Scapula Tertullus, Proconful of Africa, translated by Sir David Dalrymple, 12mo. Edin. 1790, inscribed to Dr John Butler, bishop of Hereford; preface, pp. 4; translation, pp. 18; original, pp. 13; notes and illustrations,

pp. 135.
This address contains many particulars relating to the church after the third century. The translator has rejected all words and phrases of French origin, and written entirely in the Anglo Saxon dialect. In the course of the notes many obscurities of the original, not adverted to by other commentators, are explained. Some strange inaccurácies of Mr Gibbon are also detected, not included in the mifrepresentations of his two

famous chapters.

This was the last work of this truly learned, respectable, and useful man. Whether he left behind him any thing elfe finished for the press, is known only to his friends. We have repeatedly heard that he was engaged in examining the authenticity of the books of the New Testament, and that, with the exception of two or three, he found every verse contained in it in the writings of the first three centuries. This feems indeed to have been an object in all his works; for, at the end of each of his translations and editions of the primitive Christian writers, a table is given of passages quoted or mentioned by them. If his Lordship completed any work of this kind, it should not be withheld from the public. We may indeed be told that its utility is in a great measure superseded by the laborious collections of Lardner (B), and the more elegant work of Paley (c); but not to mention the prejudices generally entertained against Lardner on account of his evident bias to Unitarianism, it would surely be proper, in the present age of wild opinions, to shew the multitude,

who are guided by authority, how important a subject Damien the Christian religion was deemed by this learned and

accomplished layman.

DAMIENS (Robert Français), as he possessed neither literature nor science, is not, strictly speaking, intitled to notice in this Work. His character, however, was so extraordinary, and the noise which he made in the world fo great, that a short account of his life will probably be acceptable to a numerous class of our

He was born in 1714 in the suburbs of Arras, called St Catharines. His infancy announced what he would one day become; for fuch were his wickedness and knaveries, that they procured to him the appellation of

Robert the Devil.

He ferved in the army, was at feveral engagements, and at the fiege of Philipsburgh. On his return to France, he entered in quality of a domestic into the college of Jesuits at Paris, which he left in 1738 to be

After having served different masters in the capital, and poisoned one of them by a glyster, he committed a robbery of 240 louis d'ors; which being discovered obliged him to abfcond. He lurked, therefore, about five months in the neighbourhood of St Omer, Dunkirk, and Bruffels, holding always the most abfurd purposes with regard to the disputes which at that time. divided France. At Poperingue, a small town near Ypres, he was heard to fay: "If I return to France-Yes, I will return, I will die there, and the greatest man on earth shall die likewise, and you shall hear news of me!"

It was in the month of August 1756 that he uttered these extravagant sentiments. On the 21st of December, in the same year, being at Falesque near Arras, at the house of one of his relations, he talked in the fame strain, affirming, "That the kingdom, his wife, and daughter, were all ruined!" His blood, his heart, and his head, were at this time in a dreadful state of effervescence; and in this state of mind he set out for Paris, at which he arrived on the 31st day of the same month. Having appeared at Versailles on the first day of the year 1757, he took opium for two or three days, probably with a view to invigorate his mind for the horrid purpose, which he executed on the 5th of January, about three quarters of an hour after five in the even-

ing.
i'his execrable parricide struck Louis XV. with a knife in the right fide, as that monarch, furrounded by his courtiers, was entering a carriage to go to Trianon. He was seized upon the spot; and after having undergone some interrogatories at Versailles, was fent to Paris to the tower of Montgommeri, where a room was prepared for him, above that which Ravaillac had formerly occupied. The king charged the great court of parliament to institute his process; but notwithstanding the most cruel tortures, which he supported with unparalleled firmness, they could not get from him a fingle confession which could lead them to fuspect that he had any accomplices. This miserable

wretch

(c) See his Evidences of the Christian Religion, in 2 vols 8vo.

⁽B) See his Credibility of the Gospel History, and other works, in 11 vols 8vo.

iens, wretch protested, that if he had been blooded as copiously as he wished, he would never have committed the crime. After being cruelly tortured to no purpose, he was condemned to die by the same punishment as the infumous affaffin of Henry IV.

The same year, on the 28th of March, which was the day of his execution, he arrived at the Place de Greve at a quarter past three, looking with a tearless eye and a firm countenance on the place and the inftruments of his punishment. They first burned his right hand, afterwards tore his flesh with red hot pincers, and poured melted lead, wax, and pitch, into the wounds. They then proceeded to quarter him, the four horses trying in vain for 50 minutes to dismember his body. At the end of that time, Damiens being fill alive, the executioners cut with knives the flesh and tendinous joinings of his legs and arms; which they had formerly been obliged to do to Ravaillac. They began with his legs; and even after they were cut, he continued to breathe till his arms were cut in like manner. His punishment, from the time he was put upon the feaffold to the moment of his death, lasted about an hour and a half; during the greater part of which he retained his recollection, and raifed his head feven or eight times to view the horses and his mangled and burned limbs. In the middle of the most violent of the tortures, he even let fome jokes escape him.

That the crime of Damiens was of the deepest dye, every man, but an affaffin like himfelf, will readily acknowledge; but the cruel and lingering punishment which was inflicted on him, was fuch as we think no human being intitled to inflict on another. It was likewife impolitic as well as cruel. We can conceive no reason for lengthening out any punishment, or accompanying it with circumstances of horror, but to infpire the spectators with a detestation of the crime; but a punishment too fevere produces a contrary effect, by withdrawing the attention from the crime to the criminal, and exciting compassion for his sufferings, and indignation against the authors of them. Such at least would be its effect in this country; but the minds of Frenchmen seem to be differently constituted from those of Britons.

Damiens was rather above the middle fize: he had a long face, a bold and piercing countenance, and his month was a little funk. He had contracted a kind of convultive motion, by a custom he had of speaking to himself. He was full of vanity, desirous of fignalizing himself, curious of novelty; a stickler against government, though filent; converfing with himfelf internally; obstinate in profecuting whatever he projected; bold to put it into execution; full of effrontery, and a liar; by turns religious and wicked; committing faults at one time, and immediately after repenting of them, and continually agitated by violent impulses. "His crime (fays a writer of genius) cost us as many groans as improbable projects of his came to light."

How, it has been asked, could a nation so mild and so polished as France, or an age which was called philosophic, produce an affaffin of a king so much beloved by his people?

To this question, the French anthor, whose work we have translated, answers, That at all times there have been wretches, who have taken neither of their age nor their country. A man, from the dregs of the people,

SUPPL. VOL. I. Part II.

accustomed to crimes, heated by the proposals of some Damiens, turbulent spirits, in the time of contests which agitate Dangeau. both the church and the state-will end in a parricide. IHis brain is heated; he puts himself into a ferment of despair, produced by misery, by the fear of the punishment his robberies deserve, and by seditious discourses. Agitated more and more by the contradictory movements which his mind experiences, and meditating on a project of this nature, his mind goes astray as far as it can, and in the height of his frantic delirium, he perpetrates the crime, just as a mad dog precipitates himself upon the first object he meets.

This is perhaps the best account which could be given, at the time it was written, of the conduct of Damiens; but subsequent events have shewn that he did not in fact deviate fo much as was supposed from the principles of his age and country, though that age was philosophic, and that country highly polished. We have seen a descendant of Louis XV. possessed of ten times his virtues, and entitled to the love and gratitude of the whole nation, murdered openly in the midst of his capital, under the forms of justice, and with circumstances of atrocity, at which the mind of Damiens would perhaps have recoiled. The guilt of an infane assassin, who commits a murder in a st of frenzy, finks into infiguificance when compared with that of legislators, who coolly departed, not only from every principle of justice, but also from the very letter of that law which conferred authority on themselves, to cut off their innocent, their amiable fovereign.

DANGEAU (Louis Courcillon de), member of the French academy, Abbe of Fontaine Daniel and of Clermont, was born at Paris in January 1643, and died there the 1st of January 1723, aged 80. Few people of family have given fo much time to the belles lettres, or paid such attention to rendering the study of them easy and agreeable. He devised several methods for rendering of more eafy acquifition the knowledge of history, painting, geography, genealogy, the interests of princes, and French grammar. He published some tracts upon each of these subjects. I. A new Method of Historical Geography, 1706, 2 vols. folio; 2. The Principles of Painting, in 14 plates, 1715, 4to.; 3. An Historical Play of the Kings of France, which is played like that of Oie, with a fmall book explaining the method; 4. Reflections on all the Parts of Grammar, 1684, 12mo. 5. On the Election of the Emperor, 1738, 8vo. The first of these, however, is his principal work, and a part of the tenth dialogue on the immortality of the foul, commonly attributed to the Abbe Choifi, is likewise his. That book is very common; but his other productions are very rare, because he only threw off a few copies for the use of his friends.

Dangeau was master of many languages; Greek, Latin, Italian, Spanish, Dutch, and almost all the languages which depend upon these. His virtues were equal to his learning. "Full of humanity for the unfortunate (fays' M. d' Alembert), he distributed succour to the indigent, and had the virtue to conceal his good actions. His heart was formed for friendship. If he had any faults, they were perhaps too great indulgence for the faults and failings of mankind; a fault which, from its rarity, may be called a virtue, and for which few people have any reason to reproach themselves, even towards their friends. He possessed, in a high degree,

Dangeau, that knowledge of men and the world which neither books nor genius alone can give when one has neglected to live with his equals. Rejoicing in the efteem and confidence which he poffeffed in a great degree in France, there could be no better counfellor than he in the most important concerns. Yet his noble foul, delicate and honourable, was ignorant of deceit; and his prudence was too evident to be taken for finesse. Pleafant and agreeable in conversation, but preferring truth in all cases, he never disputed unless there was occasion to defend it, which he did in fuch a firm manner as to give some people an idea that he was obstinate in disputing, which is feldomer found among men than a cool and

culpable indifference."

DANGEAU (Philippe de Courcillon Marquis de), brother to the former, was born in 1638. The elegance of his wit and person advanced him at the court of Louis XIV. and his decided tafte for letters procured him a place in the French academy and in that of sciences. He died at Paris in 1720, at the age of 82, chevalier of the order of the king, and grand master of the royal and military orders of our lady of Mont-Car-mel and of Saint Lazarus of Jerusalem. When he was invested with this last dignity, he paid more attention than was formerly done to the choosing of chevaliers; he renewed the ancient pomp of their admission, which the public, always malicious, ridiculed. But that which should have screened him from ridicule was, that it procured him the foundation of 25 commanderies, and he employed the revenues to bring up 12 young men of the best nobility in France. Even envy then excused his elevation. At the court (says Fontenelle), where credit is never given to probity and virtue, he held always a fair and unblemished reputation. His conversation, his manners, were all regulated by a politeness, which was not the consequence merely of his affociating with good company, but the offspring of an obliging and benevolent heart. We should pass over in him, on account of his honourable manners, the defire he had to be a great lord. Madame de Montespan, who did not believe he could play this part, used to say in a malicious manner, that one could not help loving and despising him at the same time. He married, first Françoise Morin, sister to the Marechal d'Estrées, and afterwards the Countess de Leuvestein, of a very noble house, but not opulent.

There are extant manuscript memoirs by the Marquis Dangeau, in which there are feveral curious anecdotes of Voltaire, Henault, and Beaumelle. Dangeau, however, did not always write these memoirs; which, according to the author of the age of Louis XIV. were compiled by an old valet de chambre, who inferted in them, without order, every ridiculous thing which he heard in the antichamber, or read in the gazettes. There still remains a fmall work of Dangeau's, which paints, In an interesting manner, Louis the XIV. as he was in

the midst of his court.

DARCY (Count), an ingenious philosopher and mathematician, was born in Ireland in the year 1725; but his friends being, like many other great and good families at that period, attached to the house of Stuart, he was at 14 years of age fent to France, where he spent the rest of his life. Giving early indications of a genius for science, he was put under the care of the celebrated Clairaut (fee CLAIRAUT, Encycl.), under whose tuition he improved fo rapidly in the mathematics, that at 17 years

of age he gave a new solution of the problem concerning the curve of equal pressure in a resisting medium. This was followed the year after by a determination of the curve described by a heavy body, sliding by its own weight along a moveable plane, at the fame time that the pressure of the body causes a horizontal motion in

the plane.

Though Darcy ferved in the war of 1744, he found leisure, during the buftle of a military life, to send two memoirs to the academy: the first of these contained a general principle in mechanics, that of the prefervation of the rotatory motion; a principle which he again brought forward in 1750, by the name of the principle of the preservation of action. He was taken prisoner in this war by the English; and such was either the respect paid to science, or the mercy of the cabinet of St James's, that he was treated, not as an Irish rebel, but as a French subject fighting for his king and his

In 1760, Darcy published An Essay on Artillery, containing fome curious experiments on the charges of gunpowder, &c. &c. and improvements on those of the ingenious Robins; a kind of experiments which our author carried on occasionally to the end of his life. In 1765, he gave to the public the most ingenious of all his works, his Memoir on the Duration of the Sensation of Sight; in which he endeavours to prove, and indeed completely proves, that a body may fometimes pass by our eyes without producing a sensation attended with consciousness or marking its presence, otherwife than by weakening the brightness of the object which it may chance to cover in its passage. If in this work he shall be thought to have taken hints from Dr Hartley, it is not perhaps too much to fay, that fome of our most celebrated writers on vision have since been beholden to Darcy. No man indeed has cause to be ashamed of being indebted to him; for all his works display in an eminent degree the union of genius and philosophy; but as he measured every thing upon the largest scale, and required extreme accuracy in experiment, neither his time, fortune, nor avocations, allowed him to execute more than a very fmall part of what he projected.

In his disposition, Darcy was amiable, spirited, lively, and a lover of independence; a passion to which he nobly facrificed, even in the midft of literary fociety .-He died of a cholera morbus in 1779, at 54 years of age. He was admitted of the French academy in 1749, and was made pensioner-geometrician in 1770. His essays, printed in the Memoirs of the Academy of Sciences, are various and very ingenious, and are contained in the volumes for the years 1742, 1747, 1749, 1750, 1751, 1752, 1753, 1754, 1758, 1759, 1760, 1765, and in tom. 1. of the Savans Etrangers.

DATA of Euclid, the first in order of the books that have been written by the ancient geometricians, to facilitate and promote the method of resolution or analysis. In general, a thing is faid to be given which is either actually exhibited, or can be found out, that is, which is either known by hypothesis, or that can be demonstrated to be known: and the propositions in the book of Euclid's data flew what things can be found out or known, from those that by hypothesis are already known: fo that in the analysis or investigation of a problem, from the things that are laid down as given

enton or known, by the help of these propositions, it is demonstrated that other things are given, and from these last that others again are given, and so on, till it is demonstrated that that which was proposed to be found out in the problem is given; and when this is done, the problem is folved, and its composition is made and derived from the compositions of the data which were employed in the analysis. And thus the data of Euclid are of the most general and necessary use in the solution

of problems of every kind.

Marinus, at the end of his preface to the data, is mistaken in afferting that Euclid has not used the fynthetical, but the analytical method in delivering them: for though in the analysis of a theorem, the thing to be demonstrated is assumed in the analysis; yet in the demonstrations of the data, the thing to be demonstrated, which is, that fomething is given, is never once affumed in the demonstration; from which it is manifest, that every one of them is demonstrated fynthetically: though indeed if a proposition of the data be turned into a problem, the demonstration of the proposition becomes the analysis of the problem. Simpson's Preface to

his edition of the Data.

DAUBENTON (William), who made fo much noise early in this century, was born at Auxerre. He followed King Philip V. whose confessor he was, into Spain. He had the greatest influence with that prince until the courtiers, jealous of his power, prevailed upon the king to fend him from court in 1706. By dint of folicitations, however, he was recalled in 1716, reinstated in his office, and then enjoyed more power than before. It is faid, that when Philip V. difgusted with his throne, wished to abdicate it, he confided his defign to Daubenton; that the latter, fearing that he should be obliged to follow him to his retreat, discovered this fecret to the Duke of Orleans, regent of France, who was at that time projecting the double marriage of Mademoiselle de Montpensier his daughter, with the Prince of the Asturias, and that of Louis the XV. with the infanta, five years of age. It is added, that the Jesuit believed it would be for the interest of the Duke of Orleans to diffuade Philip from his purpose; that the Duke of Orleans sent the confessor's letter to the king, who shewed it to Daubenton, without saying a fingle word; that the confessor put a very different construction upon it; that an apoplexy seized him on going out of the chamber; and that he died a short time after in 1723, in the 75th year of his age. flory (for the truth of which we will avouch still the less, that it is not mentioned by the Marshal de Noailles in his memoirs) is related by the author of the Age of Louis XV. who quotes the civil history of Bellando, page 306, Part IV. It is only clear from the memoirs of Noailles, that Daubenton opposed the abdication of the King of Spain. The Abbe Großer, in a letter inferted in the Année Litteraire (1777, No 18.), denies, 1mo, That Daubenton had revealed to the regent any secret entrusted to him by Philip V. in confession. 2do, That this Jesuit died, as Voltaire makes him from the authority of Bellando, an inaccurate historian, whose works were suppressed in Spain. 3tio, He pretends that Daubenton, far from being a man of intrigue, an ambitious monk, and capable of opposing the abdication of Philip, in order to prevent himself from being removed from court, had folicited permission to leave

it several years before. We refer the reader to that Decimals letter, which deserves to be read for the found criticism which it contains. This Jesuit had preached with some success. There are extant some tolerable funeral orations of his, and a life of St Francois Regis,

CIRCULATING DECIMALS, called also recurring or repeating decimals, are those in which a figure or several figures are continually repeated. They are distinguished into fingle and multiple, and these again into pure and mixed.

A pure fingle circulate is that in which one figure only is repeated; as .222 &c. and is marked thus .2.

A pure multiple circulate is that in which feveral figures are continually repeated; as '232323 &c. marked .23; and .524524 &c. marked .524.

A mixed single circulate is that which confifts of a terminate part, and a fingle repeating figure; as 4.222

&c. or 4.2. And

A mixed multiple circulate is that which contains a terminate part with feveral repeating figures; as \$5.524.

That part of the circulate which repeats is called the repetend; and the whole repetend, supposed infinitely continued, is equal to a vulgar fraction, whose numerator is the repeating number or figures, and its denominator the same number of nines: so $\cdot 2$ is $= \frac{2}{0}$; and $\cdot 23$

is = $\frac{23}{00}$; and $\frac{524}{000}$ is = $\frac{524}{000}$.

It seems it was Dr Wallis who first distinctly considered or treated of infinite circulating decimals, as he himself informs us in his Treatise of Infinites. Since his time many other authors have treated on this part of arithmetic; the principal of these, however, to whom the art is mostly indebted, are Messrs Brown, Cunn, Martin, Emerson, Malcolm, Donn, and Henry Clarke; in whose writings the nature and practice of this art may be fully feen, especially in the last mentioned inge-

DEFERENS, or DEFERENT, in the ancient aftronomy, an imaginary circle, which, as it were, carries about the body of a planet, and is the same with the eccentric; being invented to account for the eccentri-

city, perigee, and apogee of the planets.

DEFLECTION, the turning any thing afide from its former course by some adventitious or external cause. The word is often applied to the tendency of a ship from her true course by reason of currents, &c. which turn her out of her right way. It is likewise applied by astronomers to the tendency of the planets from the line of their projection, or the tangent of their orbit.

See ASTRONOMY in this Supplement.

DEJECTION, in astrology, is applied to the planets when in their detriment, as altrologers speak, i.e. when they have lost their force or influence, as is pretended, by reason of their being in opposition to some others which check and counteract them. Or it is used when a planet is in a fign opposite to that in which it has its greatest effect or influence, which is called its exaltation. Thus, the fign Aries being the exaltation of the fun, the oppolite sign Libra is its dejection.

DELIACAL PROBLEM, a celebrated problem among the ancients, concerning the duplication of the cube.

DEMI-BASTION, in fortification, a bastion that has only one face and one flank.

DENDROMETER, in its usual acceptation, is the name of an inftrument for measuring trees, of which the reader will find a description in the Encyclopædia Britannica. The same name has been lately given, by WILLIAM PITT, Esq; of Pendeford, near Wolverhamp. ton, to an instrument proposed by him for measuring distances by one observation.

The idea of fuch an instrument is not new. It has been frequently discussed, both in conversation and upon paper; but has been generally treated by found mathematicians with contempt, on the supposition of its being founded on false principles. Of all this our author is fully aware; but he, notwithstanding, strongly recommends it to the attention of the ingenious mathe-

matical instrument-maker.

To determine distances by one observation, two methods may be proposed, founded on different principles; the one on the supposition of the observer being in the centre, and the object in the circumference, of a circle; the other, on the contrary supposition, of the observer being in the circumference, and the object in the

To determine the distance of any object on the first supposition, the bulk or dimensions of such object must be known, either by measure or estimation, and the angle formed by lines drawn to its extremities being taken by an accurate inftrument, the diftance is eafily calculated; and fuch calculations may be facilitated by tables or theorems adapted to that purpose. For this method our prefent instruments, with a nonius, and the whole very accurately divided, are fufficient; the only improvement wanting fecms to be the application of a micrometer to fuch instruments, to enable the observer to read his angle with more minute accuracy, by afcertaining, not only the degrees and parts of a degree, but also the minutes and parts of a minute.

As in this method the bulk of inacceffible objects can only be estimated, the error in distance will be exactly in the proportion of the error in such estimation; little dependence can therefore be placed on distances thus afcertained. For the purpofcs of furveying, indeed, a staff of known length may be held by an assistant; and the angle from the eye of the observer to its two ends being measured by an accurate instrument, with a micrometer fitted to afcertain minutes and parts of a minute, diftances may be thus determined with great accuracy; the application of a micrometer to the theodolite, if it could be depended upon, for thus determining the minute parts of a degree, in small angles, is very much a defideratum with the practical furveyor.

This method of measuring distances, though plain and simple enough, our author illustrates by an example: Suppose A, fig. 1. (see Plate XXI.) the place of the instrument; BC the assistant's staff, with a perpendicular pin at D, to enable the affistant to hold it in its right position; now, if the angle BAC could, by the help of a micrometer, be ascertained to parts of a minute, the distance from A to B, or to C, might be casily calculated by the rules of plane TRIGONOMETRY; for which sce that article in the Encyclopædia.

But this method of afcertaining distances cannot be applied to inaccessible objects, and it is moreover subject to the inconvenience of an affiftant being obliged to go to the object whose distance is required (an inconvenience almost equal to the trouble of actual admeasurment); therefore the perfection of the second Dendrom method proposed, if attainable, is principally to be defired; namely, that of conceiving the observation made on the circumference of a circle, whose centre is in the object whose distance is to be ascertained; and, none of our inftruments now in use being adapted to this mode of observation, a new construction of a mathematical inftrument is therefore proposed, the name intended for which is the dendrometer.

Our author admits, that this name is not now used for the first time, though he thinks that the principle has never been applied in practice, for the familiar purpose of ascertaining terrestrial distances, in surveying, or otherwife, though the same principle has been so generally and fuccessfully applied in determining the diftance of the heavenly bodies by means of their parallax.

The following principles of construction are propofed, which may perhaps be otherwise varied and improved. O, fig. 2. the object of whose diffance is required; ABCDE the instrument in plano; BC a telescope, placed exactly parallel to the side AE; CE an arch of a circle, whose centre is at A, accurately divided from E in degrees, &c.; AD an index, moveable on the centre A, with a nonins scale at the end I), graduated to apply to the divisions of the arch; also with a telescope, to enable the observer to discriminate the object, or any particular part or fide thereof, the more accurately. The whole should be mounted on three legs,-in the manner of a plain table or theodolite, and furnished with spirit-tubes to adjust it to an horizontal position. The instrument being placed in such position, the telescope BC must be brought upon the object O, or rather upon some particular point or side thereof; when, being there fastened, the index AD must be moved till its telescope exactly strikes the same point of the object; then the divisions on the arch ED mark out the angle DAE, which will be exactly equal to the angle BOA, as is demonstrated in the XV. and XXIX. propositions of Euclid, Book I.; and the fide BA, as well as the angles ABO, and BAO, being already known, the diffance BO or AO may be eafily

As the perfection of this inftrument depends altogether upon its accuracy in taking small angles, so that accuracy must depend, not only upon the instrument's being properly fitted with a micrometer, but also in some measure upon the length of the line BA in the figure. That line, therefore, might be extended, by the instrument being constructed to fold or slide out to a greater length when in use; upon which principle, connected with the application of a micrometer, an accurate and useful instrument might certainly be constructed. To adjust such instrument for use, let a staff be held up at a distance, in the manner of fig. 1. exact. ly equal in length to the distance of the two telescopes, and the index AD being brought exactly upon the fide AE, if the two telescopes accurately finike either end of the staff, the instrument is properly adjusted.

The construction of a fimilar instrument, on the principles of Hadley's quadrant, for naval observations, would also doubtless be an acceptable object in navigation, by enabling the mariner to afcertain the diftances of ships, capes, and other objects, at a single obfervation; and that, perhaps, with greater accuracy

For

than can be done by any method now in use.

For this purpose, the following construction is proposed: ABCDE, fig. 3. the instrument in plano; O the object whose distance is required; at A, at C, at E, and at 3, are to be fixed speculiums, properly framed and fitted, that at 3 having only its lower part quickfilvered, the upper part being left transparent to view the object; the speculum at A being fixed obliquely, so that a line A 1, drawn perpendicular to its surface, may bifect the angle BAC in equal parts; that at C being perpendicular to the line C2; those at E and 3 being perpendicular to the index E 3, and that at E being furnished with a fight; the arch DC to be divided from D in the manner of Hadley's quadrant; the movement of the index to be measured as before by a micrometer; and as the length of the line AE would tend to the perfection of the instrument, it may be constructed to fold up in the middle, on the line C 2, into less compass when not in use. The instrument may be adjusted for use by holding up a staff at a distance, as before proposed, whose length is exactly equal to the line AE.

To make an observation by this instrument, it being previously properly adjusted, the eye is to be applied at the fight in the speculum E, and the face turned towards the object; when the object being received on the speculum A, is reflected into that at C, and again into that at E, and that at 3 on the index; the index being then moved till the reflected object in the speculum at 3 exactly coincides with the real object in the transparent part of the glass, the divisions on the arch D 3, fubdivided by the micrometer, will determine the angle DE 3 = the angle AOE; from which the diftance O may be determined as before.

DENOMINATOR OF A RATIO is the quotient arifing from the division of the antecedent by the consequent. Thus, 6 is the denominator of the ratio 30 to 5, because 30 divided by 5 gives 6. It is otherwise called the exponent of the ratio.

DEPRESSION OF A STAR, or of the Sun, is its distance below the horizon; and is measured by an arc of a vertical circle, intercepted between the horizon and

the place of the star.

DEPRESSION of the Visible Horizon, or Dip of the Horizon, denotes its finking or dipping below the true horizontal plane, by the observer's eye being raised above the surface of the sea; in consequence of which, the observed altitude of an object is by so much too

DEROOBUST, in Bengal, Entire; as an entire

district, opposed to KISMUT, which see.

DESAULT (Peter Joseph), surgeon in chief to the Hospital of Humanity, formerly the Hotel-Dieu at Paris, was born on the 6th of February 1744 at Magny Vernois, a village in the neighbourhood of Lure, in the department of Haute Saone (formerly the province of Franche Comté). His father and mother were in that fituation of life which is removed from want, and yet does not dispense with labour; he himself was the youngest child of a numerous family.

At Lure, under the direction of a private instructor, he was taught the first rudiments of the Latin tongue; his parents afterwards confided him to the care of the Jesuits, then almost exclusively entrusted with the education of youth in the public schools. This celebrated fociety, prompt in discovering, as expert at developing,

and adroit in appropriating talents, foon diftinguished Default. the young fludent from the crowd; and he, in his turn, was not displeased with the life he led in one of their seminaries.

On the completion of his studies, his father, who had deflined him for the church, intimated a wish that he should apply himself to theology; but his genius had taken a different direction, and he was averse to the profession of an ecclesiastic: in short, young Default declared that he was determined to betake himself to the study of the healing art; and, after a long and ineffectual refiftance on the part of his family, he was fent to Béfort, in order to serve an apprenticeship, as it was then termed, in the military hospital of that place. He accordingly spent three years there, during which he acquired fome knowledge of anatomy, attended to the dreffing of the patients, and endeavoured to supply, by his own observations, what was wanting in his instruc-

In the midft of these professional labours, his mind frequently rambled towards another icience but little connected with furgery: this was mathematics, the elements of which he had acquired among the Jesuits. His progress in this favourite study was rapid; but he fell into one of the many errors fo common among the physicians of that day: this consisted in a false application of the rules of geometry to the laws of the animal

He not only perused with avidity the treatise of Borelli De Motu Animalium, but actually translated the whole of it, and even added a commentary, still more abundant in calculation than that of the celebrated pro-

fessor of Naples.

His fuccess in a branch of physiology so much cultivated at that time, attracted the attention of one of his fuperiors, a zealous partizan of the doctrine of the mechanicians, who wished to attach him to his person; but his defire of fame required a more extensive theatre, and his love of study made him folicitous of better means of instruction. Paris presented both these advantages, and he accordingly repaired thither in 1764, at the age of nineteen, in fearch of them.

Surgery at that period flourished in the capital under the auspices of a Lafaye, a Morand, an Andouillet, and a Louis. The fight of fuch great masters excited the genius of those who aspired to emulate them: young Default deemed himself worthy of equalling men whom other students were content with only admiring. Animated by this fentiment, he entirely refigned himself to his ardour; anatomy became the special object of his labours, and his diffections were not confined to the human body, for he investigated, by means of his knife, a prodigious number of animals of all kinds: at first, from a difficulty of procuring human subjects, and afterwards on account of the advantages which he experienced from this general method. In order to become intimately acquainted with our own organization, it is necessary to compare it with whatever has a resemblance to it in other bodies.

He accordingly spent the greater part of the day in the amphitheatres. The hours stolen from his favourite labours were employed in attending the hospitals; he was the first at the bed of the patient where an operation was to be performed, and was fure to be present at the dreffings, on purpole to examine the refult. The

infirmities

ferved him as the best treatife for curing them; and the great furgeous of all nations have formed their mode of practice by contemplating the same book.

But he reckoned too much on a robust and vigorous temperament; for, after two years close and affiduous application, he fell into a cachectical habit of body, which had nearly proved mortal, and which confined him for almost twelve mouths to his bed; but at length, ewing partly to the vigour of his youth, and partly to the attention of his young friend Chopart, his inseparable companion in his operations, who attended him alfo during his last illness, and only survived him a few days, he was so fortunate as to recover.

Restored to life, he forgot that an excess of attention had conducted him to the very gates of death; a new career opened to his view, and required new efforts on his part. In the winter of 1766 he commenced a course of anatomy, and soon reckoned 300 pupils, most of them older than himself, who were attracted by the clearness of his demonstrations, the methodical arrangement of his descriptions, and, above all, by his indefatigable zeal in the science of instruction.

His fuccels inspired the privileged professors, whose schools became deserted, with jealoufy and revenge; they employed the authority of the corporation against him, and would have nipped his efforts in the bud, had it not been for the protection of Louis and Lamartiniere, who were zealous of protecting a youth of talents, whose fole reproach was, that he had not wealth enough to purchase certain franchises. After all, had it not been for the permission he obtained of borrowing the name of a celebrated physician, he must have actually defifted from his lectures.

Default's reputation now began to be buzzed about, and a multitude of patients claimed his affiftance; but he constantly refused to practise until he should be placed at the head of some great establishment.

At length, at the repeated folicitations of his friends, he presented himself as a candidate to the corporation of furgeons; and they, much to their honour, admitted him in 1776, on condition of paying the usual fees when convenient. The following is the title of his thefis: " De calculo vesica urinaria, eoque extrahendo, pravid sectione, ope instrumenti Haukensiani emendati."

14is public lectures were accompanied with as much celebrity as his private ones. Brilliant discoveries were not the object of his anatomical labours, which were always connected with the art of healing: he was, however, the first man in France who taught surgical anatomy

After becoming first a simple member, and then a counsellor, of the perpetual committee of the academy of furgery, he was appointed chief furgeon to the hofpital of the college, and confulting furgeon to that of St Sulpice: neither of these added any thing to his

Default. infirmities of mankind, sterile in respect to the vulgar, fortune, but they gave him a clear infight into practice, Default and enabled him to judge of cases by the inductions arifing from his own experience.

In 1779 he invented the bandage now in use for fractures; by means of which, the fragments being kept in a state of perpetual contact, become consolidated, without the least appearance of deformity, an almost in-

evitable confequence of the former mode.

On his appointment to the place of furgeon major to the hospital de la Charité, in 1782, he introduced a new method of treatment in oblique fractures of the thigh-bone; and he also healed, by means of a methodical compression, those various ulcers whose cure had hitherto been attended with great difficulty. In addition to this, he substituted new bandages in fractures of the humerus and clavicle, and adopted a new mode of treating the hare-lip, superior to that used by Louis. He never recurred to amputation but in extreme cases, when there was a certainty that diffolution would have followed a neglect of the operation.

When a premature death carried off Ferrand, chief furgeon of the Hotel-Dieu in Paris, Default was confidered as the most proper person to succeed him; and, on the demife of Moreau, the whole charge of the hofpital devolved on him. After three years of solicitations and disputes, he at length in 1788 proceeded in his long-projected scheme of establishing a clinical school; and a spacious amphitheatre was accordingly erected for that purpose. Scarcely had his first (A) course commenced, when the number of pupils who flocked around him was really aftonishing. Poreigners repaired from all parts, and feveral of the neighbouring states fent students to Paris, expressly for the purpose of affifting at his demonstrations. More than 600 auditors constantly attended, in order to learn a new fystem, consisting of a simple mode of treatment, disengaged from ancient prejudices, and a complex incoherent practice.

A few of his improvements are here specified.

1. The method of ligature employed by the ancients in the cure of umbilical hernias of children, having been generally omitted in the practice of the moderns, he again introduced and perfected this mode, and demonstrated, by his fuccess, its superiority over compressive

2. He was one of the first men in France to extract

the loofe cartilages (cartilages flottans) in joints. 3. He employed a new treatment, that of a methodi-

cal compression, in respect to schirrosities of the rectum; in order to which he introduced a candle or bougie, the fize of which he gradually augmented.

4. He simplified, and rendered more commodious, the

reduction of luxations of the humerus.

5. Fatal experience having pointed out the danger of employing the trepan in wounds of the head, he tubstituted another method of treatment (l'usage de l'émétique) now adopted by many practitioners.

6. He

⁽A) The business of the day was conducted in the following routine: 1. A public consultation concerning the indigent out-patients. 2. The young practitioners belonging to the hospital read a detailed account of all the interesting cases of such patients as were to be discharged that day. 3. The operations: each of these was preceded by a differtation on the state of the patient, who was then carried to the amphitheatre, where Desault, attended by his affiftants, performed the operation in presence of all the pupils. 4. Argumentative details, by the professor, either on the dangerous maladies existing in the hospital, or on the situation of the patients on whom operations had been performed during the preceding day. 5. The diffection of subjects. And, 6: A keture on some particular branch of pathology.

6. He made feveral very useful improvements on chirurgical inftruments; fuch as those employed in the cases of polypus in the womb and nostrils (la pince à gaine et des porte-næuds pour la ligature des polypes, &c.); for cutting through obstructions in the different cavities (le kiotome); and for the fifula in ano. In cases of incision he introduced the use of the instrument (le gorgeret) invented by Marchetti, well known among foreigners, but almost totally neglected in France before this period.

He at the same time retrenched the use of a great number of superfluous ones, and banished all practices attended with greater pain than utility. Avoiding every thing that was complex, he proved that the art of healing, in imitation of nature, ought to be simple in

its means, and fruitful in its resources.

In 1791 he published his Journal de Chirurgerie, which was edited by his pupils, and destined to describe the most interesting occurrences in his school, and also extracts from his lectures, which were then dedicated to the investigation of the maladies incident to the uri-The treatment of these diseases, hinary passages. therto the reproach of practitioners, had been much improved by the affiftance of the artift Bernard. The elastic probes (les sondes élastiques), on their first appearance, fixed the attention of all professional men; but none knew better than Default how to appretiate their advantages. By means of them, he introduced a novel mode of cure in contractions of the urethra, which faved a great number of lives every year in the Hotel-Dieu. But he did not confine their use to the diseases of the urethra alone, for he employed them to remove the divers obstacles that impede deglutition or respiration.

In the midst of such a multiplicity of labours, and although he was obliged to attend 400 fick twice aday, Default nevertheless employed more than four hours

of his time in visiting private patients.

Few furgeons ever enjoyed fuch an exclusive share of public confidence; few ever possessed similar means of enriching themselves; and yet he neglected for a long time to take advantage of this. Had he been less ardent for glory, he would have been more favoured by fortune; but he facrificed all interested views to the noble ambition of advancing his art. His clinical and anatomical courses were gratuitously opened by him to the world after the year 1790; and while the public schools languished in the midst of troubles, inseparable perhaps from a mighty revolution, he was forming the greater part of those surgeons employed at this present moment in the numerous armies of the republic. Confidered under this point of view alone, the services which he rendered to humanity are incalculable: too happy if perfecution had not been his fole reward!

While out of mere attachment to the public weal, he council of health, conferred on him in 1792 by the minister Servan, he was denounced in the popular societies as an egotist, an indifferent, &c. and became one of the first victims of that proscription which, under Robespierre, extended to nearly every man of talents.

Chaumette accused him to the sections as having neglected the brave men wounded on the 10th of August, while they themselves were lavishing their bleffings at the Hotel-Dieu on their saviour. Twice was he brought to the bar of a commune; defirous of discovering a pre-

text for persecution, the clamours of the people were Default, unremittingly excited against him. He was at length Determicarried away from his amphitheatre, while in the very act of haranguing his pupils; and, in confequence of a mandat d'arrêt from the revolutionary committee, conducted by a body of armed men to the Luxembourg. From this horrid prison few ever departed but to meet their fate; luckily, however, his name was not yet entered on that bloody lift, in which those of Malesherbes and Lavoisier were inserted. On the contrary, at the end of three days he was liberated, and instantly refumed all his functions.

. On the establishment of L'Ecolede Santé, Desault was appointed clinical professor; and for external maladies he foon after obtained from the government the conversion of the Eveché into an hospital for surgical

In the midst of these plans, the troubles that occurred in the month of May unfortunately affected his mind, and made him dread left the days of profcription should return. It was in vain that his friends attempted to foothe his fufferings; for on the night of the 29th of May, a malignant fever made its appearance, and a nearly continual delirium enfued until his death, which occurred on the 1st of June 1795, on which day he breathed his last, in the arms of his pupils, at the age

The populace were perfuaded that he was poisoned. This ridiculous opinion originated in confequence of the epoch of his death, which preceded but a short time that of the son of Louis XVI. whom he had visited during his illness in the prison of the Temple. It is pretended that he fell a victim to his constant refusal to yield to the criminal views entertained against the life of that child.

Default was of a middling stature. He was well proportioned, and possessed an open countenance. His temperament, naturally robust, had been fortified by his early education, and was never fapped by an excess of pleafures, for to them his heart was always indifferent. His ruling passion was the love of glory; his favourite pursuit, the practice and advancement of his art. He was warm, nay fometimes violent; and his scholars were not always inclined to praife the sweetness of his temper. On the other hand, his mind was noble, elevated, and great, even to excess.

The French republic, eager to pay homage to his memory, has prefented his widow with a pension of 2000 livres per annum. A son, Alexis Mathias Default, was the sole fruit of his marriage; and he has left but one work behind him, in which the name of his friend Chopart is joined with his own. It is entitled Traité des Maladies Chirurgicales et des Operations qui leur convi-

ennent, 2 vols 8vo.

DETERMINATE PROBLEM, is that which has added to his various functions that of a member of the . but one folution, or a certain limited number of folutions; in contradiffinction to an indeterminate problem, which admits of infinite folutions.

DETERMINATE Section, the name of a tract or general problem, written by the ancient geometrician Apollonius. None of this work has come down to us, excepting some extracts and an account of it by Pappus, in the Preface to the 7th book of his Mathematical Collections. He there fays that the general problem was, "To cut an infinite right line in one point fo, that, of the fegments contained between the point of

fection-

Detons- fection fought, and given points in the faid line, either the square on one of them, or the rectangle contained by two of them, may have a given ratio, either to the rectangle contained by one of them and a given line, or

to the rectangle contained by two of them."

DETONATION (see that word Encycl.). The aftonishing violence with which the oxy-muriat of potass, when mixed with various substances, detonates, has been already noticed in this Supplement under the article CHEMISTRY, no 722, where the theory of these explosions is likewise given. But as several chemists feem to think that this falt, which decrepitates by friction, and spontaneously takes fire when mixed with fulphur, contains in itself the elements and phenomena of thunder, it will not probably be unacceptable to our readers to find, in this place, a distinct account of the various mixtures which produce its detonations. The following are the principal which have been discovered by Fourcroy and Vaquelin.

1. Three parts of the oxy-muriat of potals, and one part of powdered fulphur, rubbed together in a metal mortar, produce numerous successive explosions, resembling the fmacking of a whip, or even as loud as the report of a pillol or a mulket, according to the rapidity of the motion, and the force of the pressure made use of. A few grains of the same mixture, by being struck fmartly upon an anvil with a hammer, occasion a report equal to that of a musket; and torrents of purplish light are feen about the anvil. If this mixture be thrown into concentrated fulphuric acid, it instantly takes fire, and burns, without noise, with a slame of a

dazzling whiteness.

2. A mixture of three parts of this falt, half a part of fulphur, and half a part of charcoal, causes stronger explosions than the preceding when rubbed in a mortar, and a louder noise when struck upon an anvil. Its flame also, when the mixture is made to explode, or when it is thrown into fulphuric acid, is more rapid, more lively, and of a redder colour, than that of the

preceding.

3. A mixture of equal parts of oxy-muriat of potass and antimony in powder explodes with noise by percuffion; but produces only reddish sparks when thrown into sulphuric acid. If zinc be substituted in the place of antimony, a fimilar explosion takes place, accompanied with a white flame. Sulphuric acid has no effect upon this last mixture.

4. With regulus of arfenic, this falt explodes very violently by the stroke of a hammer; it inflames, with tingular rapidity and brilliancy, by the contact of fulphuric acid. In this last experiment there arises a smoke, which in the air takes the form of a crown, in the same manner as phosphorated hydrogenous gas does when it

inflames fpontaneously in a still atmosphere.

5. Sulphuret of iron or martial pyrites inflames rapidly, but without noise, when rubbed in a metal mortar with oxy-muriat of potals. This mixture, when ftruck upon an anvil, explodes violently, and with a red flame.

6. The red fulphuret of mercury or cinnabar, and the fulphurated calces of antimony, explode with the oxy-muriat of potals by percussion, but they do not insame by sulphuric acid. The same thing happens when charcoal alone is mixed with this falt.

Any of the following substances, namely, sugar,

gums, oils (both fixed and volatile), alcohol, ether, Deton when mixed with oxy muriat of potals, have the property of exploding very violently by the stroke of a Diabete hammer, and all of them fend forth a brisk slame at the time of their explosion. The liquid combustible substances above mentioned are to be mixed with the falt in fach a manner as to form a kind of paste. None of these mixtures explode or inslame by being rubbed in a mortar; but some of them inflame by being mixed with concentrated fulphuric acid, their combustion being slow and progressive.

8. All the substances above mentioned, which, being mixed with the oxy muriat of potals, take fire and burn instantly, and with considerable noise, by the quick pressure of the strokes of a hammer, produce a much ftronger explosion when they are so closely wrapped up in paper, two or three times doubled, as to be thereby

compressed before they are struck.

9. An electric shock from a battery of large surface, charged by a strong electric machine, causes all the forementioned mixtures to explode in the fame manner as percuffion, and their explosion is also accompanied by a

bright light.

To the above-mentioned facts, the authors add, that it was already well known, that gunpowder would explode by a violent blow, or very strong pressure; but they observe, that the stroke which is necessary for that purpose must be much stronger than that which suffices to produce an explosion in the above-mentioned mixtures of combustible substances with the oxy-muriat of potass; and that its explosion is by no means so remarkable as that which is produced by the help of this

DIABETES Mellitus (fee Medicine, nº 318, &c. Encycl.), is fo formidable a difeafe, though not very frequent, that it would be unpardonable in us not to mention every method of treating it successfully which has come to our knowledge. Since our article MEDICINE was published, Dr Rollo, surgeon general to the royal artillery, has fuggested a method of treating this difease, which in various instances has been crowned with fuccefs.

The Doctor supposes, that in this complaint the vegetable matter taken into the stomach has not, from some defect in this organ, undergone a sufficient change to form proper chyle; that in confequence of this, much faccharine matter is evolved, which, when carried into the circulation, proves a general stimulus, producing head-aches and quickness of pulse, but that it acts more remarkably on the kidneys, occasioning a constant and copious fecretion of fweet urine. From this hypothefis, he was naturally led to adopt a plan of cure, which has proved completely successful. The indications he lays down are: 1. To prevent the formation of faccharine matter in the stomach; and, 2. To remove the morbidly increased action of this organ, and restore it to a healthful condition. These indications are to be answered by a complete diet of animal food, and by the use of such medicines as shall diminish the action of the

ftomach.

nond, flomach, and at the fame time counteract the formaerot. tion of faccharine matter. The remedies employed for this purpose have been emetics, kali sulphuratum, limewater, hepatized ammonia, and vegetable narcotics. But the principal dependence is to be placed on a total abilinence from all vegetable matter, which alone can fupply the faccharine principle. By a regular perfeverance in this plan, the first of two patients was completely cured in four weeks, although the difeafe had been of feven months continuance. The urine, which at the commencement of the treatment was fweet, and amounted to 24 pints daily, was at last reduced to 11 pint, being at the fame time free from any faccharine impregnation. The fecond patient, from his age and other circumstances, although relieved from the diabetic affection, did not regain his wonted state of health; but even in this case, the effects produced by the treatment, when properly attended to, were most decidedly in confirmation of this plan of cure.

The Doctor has received feveral communications in confequence of the dispersion of the printed notes on - the first case. The most important are the result of two cases treated in this way by Dr Cleghorn of Glafgow, and one by Drs Currie and Gerard at Liverpool; all of which afford the strongest corroboration of the

efficacy of this mode of treatment.

DIAMOND, the most precious of all the gems; for the nature of which fee CHEMISTRY, no 33, &c. in this

Supplement.

DIDEROT (Dionysius) of the academy of Berlin, the fon of a cutler, was born at Langres in 1713. The Jesuits, with whom he went through a course of study, were defirous of having him in their order; and one of his uncles, deligning him for a canonry which he had in his gift, prevailed upon him to take the tonfure.

His father feems to have known him better; for perceiving that he was not inclined to be a fefuit, nor fit to be a canon, he fent him to Paris to profecute the study of the law. To the law, however, he paid very little attention, but devoted his time to science and general literature; which so offended his father, that he flopped the remittance of his pecuniary allowance, and feemed for fome time to have abandoned him.

The talents of young Diderot supplied him with a maintenance, and drew him from obscurity. According to his friends, his capacious mind embraced phyfics, geometry, metaphyfics, ethics, and the belles lettres, from the time that he began to read with reflection; and it is certain that he aspired at being a master in all these departments of literature. His bold and elevated imagination seemed to give him likewise a turn for poetry; but he neglected it for the sciences. He settled at an early period at Paris, where the natural eloquence which animated his conversation procured him friends and patrons. What first drew the attention of the public to him as an author, and gave him a high reputation among a certain class of readers, was a small volume written against the Christian religion, and intitled Pensées Philosophiques; which was reprinted afterwards under the title of Etrennes aux Esprits forts.
This book appeared in 1746, 12mo. The adepts

of the new philosophy compared it, for perspicuity, elegance, and force of diction, to the Pensées de Pascal. But the aim of the two authors was widely different; Pafcal employed his talents and his erudition, which

SUPPL. VOL. I. Part II.

was profound and various, to support and illustrate the Diderot. great truths of our holy religion, which Diderot attacked by all the difingenuous arts of an unprincipled fophist. The Pensees Philosophiques, however, became popular. It contributed to promote the object of that conspiracy which had been for some time formed against every thing which ennobles human nature (See Jaco-BINS in this Supplement). It was therefore applanded by Voltaire and D'Alembert, and read, of course, by every man and woman of taste in Paris.

Our anthor was more usefully employed in 1746, when, together with Meffrs Eidous and Touissant, he published a general Dictionary of Medicine, in fix volumes folio. This work, it must be confessed, has confiderable merit; for though there are in it feveral articles superficial and erroneous, there are many others of fuch deep and accurate disqusition, as defervedly re-

commended it to men of science.

It was about this time that an intimacy was formed between Diderot and D'Alembert, and that, under the direction of Voltaire, they formed the idea of a Didio-naire Encyclopedique. The great objects which they had in view when they entered upon this work are now univerfally known. D'Alembert was a profound mathematician, Diderot had confiderable knowledge in the phyfical fciences, more especially mechanical philosophy, and Voltaire was a mafter of the belles lettres.

It is not to be supposed that such men would publish any thing very defective in these departments of science; but an Encyclopedia must treat of religion; and to every kind of religion they were all fworn enemies. They engaged, however, a very worthy, though not very acute, clergyman, to furnish the theological articles; and for other branches of knowledge, they were promifed the affiftance of several men of letters, and of a variety of artists.

Diderot took upon himself the description of arts and trades; one of the most important departments of the work, and the most acceptable to the public. To the particulars of the feveral processes of the workmen he fometimes added reflections, speculations, and principles, adapted to their elucidation. But besides his own department, he furnished articles on almost every other

lubject. By those who knew not the great aim of the undertakers of this work, it has been regretted that Diderot was not less verbose, less of the differtator, and less inclined to digreffions. He has also been censured for employing needlessly a scientific language, and for having recourse to metaphylical doctrines, frequently unintelligible, which occasioned him to be called the Lycophron of philosophy; for having introduced a number of definitions incapable of enlightening the ignorant, and which the philosopher seems to have invented for no other purpose than to have it thought that he had great conceptions; while, in fact, he had not the art of expressing perspicuously and simply the ideas of others. But these complaints arise from mistaking entirely the purpose for which he wrote.

It has been completely proved, that one great object for which the philosophers, as they called themfelves, undertook the compilation of the Encyclopedie was to sap the foundation of all religion. This was to be attempted, not directly and avowedly; for bare-faced atheism would not then have been suffered in France. Diderot. A cloak, therefore, was to be worn, and the poisoned dagger to be concealed under it. Whilft the well-meaning divine was supporting, by the best arguments which he could devife, the religion of his country, Diderot and D'Alembert were overturning those arguments under titles which properly allowed of no such disquisitions. This necessarily produced digressions; for the greatest genius on earth could not, when writing on the laws of motion, attack the mysteries of Christianity without wandering from his fubject: but that the object of these digressions might not pass unnoticed by any class of readers, care was taken to refer to them from the articles where the question was discussed by the divine. That when employed in this way, Diderot feems to write obscurely, is indeed true; but the obscurity is not his. His atheism was fo plain, that for the most part D'Alembert, or some other leader of the gang, had to retouch his articles, and throw a mist over them, to render their intention the less obvious.

Even with all this care and studied obscurity, the defign of the Encyclopedie was too palpable not to be feen, and too wicked not to give offence. Certain wild positions on government and on religion occasioned the impression to be suspended in 1752. At that time there were no more than two volumes of the dictionary published; and the prohibition of the succeeding ones was only taken off at the end of 1753. Five new volumes then fucceffively appeared. But in 1757 a new florm arofe, and the book was suppressed. The remainder did not appear till about ten years after; and was then for a while only privately distributed; fome copies having been feized by government, and the printers shut up in the bastile. The merit, however, of fome of the articles is confessedly great; and the first

edition was quickly fold off.

Thus was this great work in the press from 1751 to 1767; during which period, Diderot and D'Alembert were accustomed to frequent the coffee-houses of Paris, and to enter with keenness into religious disputes: the former attacking Christianity; and the latter, under the mask of piety, defending it; but always yielding to the arguments of his opponent. This practice was put a stop to by the police; and Diderot, when reproached by the lieutenant with preaching atheifm, replied, "Ce-

la est vrai, je suis athée, & m'en sai gloire."

Finding his impious conversations interrupted, and the publication of the Encyclopedie rendered tedious by the vigilance of government, he thought of propagating his notions by other vehicles. Alternately ferious and sportive, solid and frivolous, he published, at the very time he was working on the Dictionary of Sciences, feveral productions, which could fearcely have been expected from a man fo completely employed. His Bijoux Indiferets, 2 vols 12mo, are of this number -a difgusting work, even to those young people who are unhappily too eager for following after licentious ro-mances. Even liere a certain philosophical pedantry appears in the very passages where it is most misplaced, and never is the author more aukward than where he intends to display a graceful ease.

The Fils Naturel, and the Pere de Famille, two comedies in profe, which appeared in 1757 and 1758, are not of the same kind with the Bijoux Indiscrets. They are moral and affecting dramas, where we see at once a nerwous style and pathetic fentiments. The former piece

is a picture of the trials of virtue, a conflict between in- Diderot. terests and passions, wherein love and friendship play important parts. It lias been faid, that Diderot borrowed it from Goldoni: but if that be the case, the copy does honour to the original; and, with the exception of a fmall number of icenes, where the author mixes his philosophical jargon with the fentiments of the heart, and some sentences out of place, the style is affecting and natural enough. In the fecond comedy, a tender, virtuous, and humane father appears, whose tranquillity is disturbed by the parental folicitudes, infpired by the lively and impetuous passions of his children. This philosophical, moral, and almost tregical comedy, has produced confiderable effects on feveral theatres of Europe. The dedication, to the princess of Nassau Saarbuck, is a little moral tract of a singular turn, without deviating from nature. This piece, written with a true dignity of style, proves that the author possessed a great fund of moral sentiments and philosophical ideas. At the end of these two pieces, published together under the title of Theatre de M. Diderot, are dialogues, containing profound reflections and novel views of the dramatic art. In his plays he has endeavoured to unite the characters of Aristophanes and Plato; and in his reflections he fometimes displays the genius of Aristotle.

This spirit of criticism is exhibited, but with too much licence, in two other works, which made a great The former appeared in 1749, 12mo. intitled Letters on the Blind for the Use of those who Sec. The free notions of the author in this work cost him his liberty. He underwent a fix months imprisonment at Viorcennes. Having naturally strong passions and a haughty spirit, and finding himself on a sudden deprived of liberty and of all intercourse with human beings, he was threatened with the loss of his reason. The danger was great; and to prevent it, they were obliged to allow him to leave his room, to take frequent walks, and to receive the vifits of a few literary men; among whom J. J. Rouffeau, at that time his friend, went and administered consolation to him, which he

ought not to have forgotten.

The letter on the Blind was followed by another On the Deaf and Dumb, for the Use of those who can Hear and Speak; 1751, 2 vols, 12mo. Under this title the author delivered reflections on metaphyfics, on poetry, on eloquence, on music, &c. In this essay there are some good things, among others absurd and impersect. Though he strives to be perspicuous, yet he is not always understood; and this is more his fault than that of his readers. Of what he has composed on abstract subjects, it has been said that it is a chaos on which the light shines only at intervals. The other productions of Diderot betray the same defect of clearness and precision, and the same uncouth emphasis, for which he has always been blamed.

The principal of them are, 1. Principles of Moral Philosophy, 1745, 12mo; of which the Abbé de Fontaine speaks well, though it met with no great success. It was our philosopher's fate to write a great deal, and not to leave a good book, or at least a book well composed. 2. History of Greece, translated from the English of Stanyan, 3 vols, 12mo; an indifferent translation of an indifferent book. 3. Pieces on several Mathematical Subjects, 1748, 8vo. 4. Reflections on the

derot. Interpretation of Nature, 1754, 12mo. This interpreter is very obscure. 5. The Code of Nature, 1755, 12mo; which is certainly not the code of Christianitv. 6. The Sixth Sense, 1752, 12mo. 7. Of Public Éducation; one of that swarm of publications produced by the appearance of Emilius, and the abolition of the Jefuits. Though all the ideas of this author could not he adopted, yet some of them are very judicious, and would be highly useful in the execution 8. Panegyric on Richardson. Full of nerve and animation. 9. Life of Seneca. This is the last work which he acknowledged; and it is one of those by Diderot that is perused with most pleature, even in rectifying the judgments he paffes on Seneca and other celebrated men. The Abbé Barruel fays, that he was the author of Systeme de in Nature, which is usually given to Robinet; and it is certain, that if he was not the author, he furnished hints, and revised the whole. Yet the junto of atheists were themselves ashamed of the first edition of that work; and after all Diderot's care to improve it, the fubsequent editions are, notwithstanding his boasted knowledge of the laws of nature, contemptible in the eyes of a real mechanical philosopher.

When a new edition of the Encyclopedie was refolved on, Diderot, the editor of the former edition, thus addresses the booksellers who had undertaken to republish it. "The imperfections (fays he) of this work originated in a great variety of causes. We had not time to be very scrupulous in the choice of our coadjutors. Among some excellent persons, there were others weak, indifferent, and altogether bad. Hence that motley appearance of the work, where we fee the rude attempt of the school boy by the side of a piece from the hand of a master; a piece of nonsense next neighbour to a sublime performance. Some working for no pay, foon loft their first tervour; others, badly recompensed, served us accordingly. The Encyclopedie was a gulf into which all kinds of scribblers promiseuously threw their contributions; their pieces ill conceived, and worse digested, good, bad, contemptible, true, false, uncertain, and always incoherent and unequal; the reference, that belonged to the very parts assigned to a person, never filled up by him. A refutation is often found where we should naturally expect a proof. There was no exact correspondence between the text and the plates. To remedy this defect, recourse was had to long explications. But how many unintelligible machines, for want of letters to denote the plates!" To this confession Diderot added particular details on various parts; such as proved that there were in the Encyclopedie subjects to be not only retouched, but to be composed afresh: and this was what a new company of literati and artiffs fet themselves to work upon in the Encyclopedie Metho-

This immense work is not yet completed; and therefore we cannot speak of it as a whole; but it is surely not less verbose than the former edition, nor do the aims of its editors appear to be purer. That it contains much valuable information in chemistry, and indeed in every department of physical science, no candid man will controvert: but its articles on abstract philosophy are prolix and obscure; and it betrays the same impiety, the fame eager defire to corrupt the principles of the riling generation, and the fame contempt for every

thing which can make mankind happy here or hereaf. Diderot. ter, with the former edition.

Notwithstanding his numerous publications, Diderot was never rich. Soon after the publication of the last volumes of the Encyclopedie, upon which he had been employed for upwards of twenty years, his circumstances were fo straitened, that an expedient was to be devifed for their improvement. He had long corresponded with the late Emprels of Russia, whom he perfuaded to confider him as the greatest, or one of the greatest economists of France. In the course of the correspondence he had mentioned his own library as one of the most valuable in Europe; and when Catharine wanted to purchase it and make him librarian, he faid that his constitution could not support the cold climate of St Petersburgh. She offered to let him keep it during his lifetime in Paris; and the library was fold for an immense price. When her ambassador wanted to see it, after a year or two's payments, and the vifitation could be no longer put off, Diderot was obliged to run in a hurry through all the bookfellers shops in Germany to fill his empty shelves with old volumes. He had the good fortune to fave appearances; but the trick took air, because he had been niggardly in his attention to the ambaffador's fecretary. This, however, did not hinder him from vifiting his imperial pupil, to whom he told a poor flory, in hopes of getting his daughter married with parade, and patronifed by her majesty; but it was feen through, and he was disappointed.

In the year 1784 Diderot's health began visibly to decline; and one of his domestics, perceiving that his death was at no great distance, acquainted him with his apprehensions, and addressed him on the importance of preparing for another world. He heard the man with attention, thanked him kindly, acknowledged that his fituation required ferioufness, and promised to weigh well what he had faid. Some time after this conversation he defired that a priest might be brought; and the same domestic introduced to him M. de Farsac, Curé de St Sulpice. Diderot faw this ecclefiaftic feveral times, and was preparing to make a public recantation of his errors. Condorcet and the other adepts now crowded about him, perfuaded him that he was cheated, that his case was not so dangerous as it was faid to be, and that he only wanted the country air to restore him to health. For fome time he refifted their attempts to bring him back to atheifm, but was at last prevailed upon to try the effect of the country air. His departure was kept fecret, and he was concealed in the country till the 2d of July, when he died. His dead body was fecretly brought back to Paris, and a report was spread and believed that he died fuddenly on rifing from the table, without remorfe, and with his atheifm unshaken.

To draw a formal character of this wretch is furely superfluous. His friends extol his frankness, his difinterestedness, and his integrity; but except his gross avowal of atheifm, which may in France be called frankness, this character is belied by every transaction of his life. He married, and had a daughter, as has been already mentioned. M. Bauzé, referred to by Ablé Barruel, coming one day into Diderot's house, found him explaining to this daughter a chapter of the gofpel. When he expressed some surprise at this conduct, Diderot said : " J'entends ce que vous voulez dire ;

Differential mais au fond, quelles meilleures leçons pourrois-je lui Method. donner, ou trouverai je mieux?" It was a common affertion of Diderot's, that between him and his dog "il n'y avoit de difference que habit." In uttering this fentiment, he refembled not Pope's Indian with untutored mind,

> "Who thinks, admitted to that equal sky, " His faithful dog shall bear him company."

The Indian hopes to carry his dog with him to heaven; but Diderot hoped to die like a dog, and to be

as if he had never been.

DIFFERENTIAL METHOD, is the art of working with the differences of quantities. By this method any term of a feries may be found from the feveral orders of differences being given; or vice versa, any difference may be found from having the terms of the leries given: it likewise shews how to find the sum of such a series. And it gives rules to find by interpolation any intermediate term, which is not expressed in the series, by

having its place or polition given.

When any feries of quantities is proposed, take the first term from the second, the second from the third, the third from the fourth, &c. then all these remainders make a new series, called the first order of differences. In this new feries take the first term from the second, the fecond from the third, the third from the fourth, &c. as before; and these remainders make another series, called the fecond order of differences. In like manner, in this feries, take the first term from the second, the second from the third, &c.; and these will make a series called the third order of differences; and after this manner you may proceed as far as you will. Thus in the following proposition A, b, c, d, e, &c. is the series; B, B², B³, B⁴, &c. the first order of differences; C, C2 C3, &c. the fecond order of differences; D, D2, &c. the third order; E, &c. the fourth order, and so on. But the first terms of these several orders of differences, as B, C, D, E, &c. are those that are principally made use of in calculations by this method.

PROP. I. If there be any feries, A, b, c, d, e, &c. and if there be taken the first differences B, B2, B3, &c. the fecond differences C, C2, C3, &c. the third differen-

ces D, D2, D3, &c. and fo on.

Then if T fland for the first term of the nth differences, $\pm T = A - nb + n \times \frac{n-1}{2}c - n \times \frac{n-1}{2}$

 $\times \frac{n-2}{3}d + n \times \frac{n-1}{2} \times \frac{n-2}{3} \times \frac{n-3}{4}e - \&c. \text{ that}$ is, + T, when n is even, and - T when n is odd.

The several orders of differences being taken as before directed, will stand thus. Then,

B3 C3

feries A , b , c , d , e, &c. 1ft diff. b-A , c-b , d-c , e-d, &c. 2d diff. c-2b+A, d-2c+b, e-2d+c, &c. 3d diff. d-3c+3b-A, e-3d+3c-b, &c. 4th diff. e-4d+6c-4b+A, &c.

That is, B=b-A, C=c-2b+A, D=d-3c+3b Differentia -A, E=e-4d+6c-4b+A, &cc. or -B=A-b, Method, +C = A - 2b + c, -D = A - 3b + 3c - d, +E = A-4b+6c-4d+e, &c. where, putting T successively equal to B, C, D, E, &c. and n = 1, 2, 3, 4, &c. the prop. will be evident.

Cor. Hence

A=A, the first term.

B = -A + b, the first difference.

C = A - 2b + c, the 2d difference.

D = -A + 3b - 3c + d, the 3d difference. E = A - 4b + 6c - 4d + e, the 4th difference.

F = -A + 5b - 10c + 10d - 5e + f, the 5th difference,

Prop. II. If A, b, c, d, e, &c. be any feries, and there be taken B, C, D, E, &c. the first of the several orders of differences;

Then, the nth term of the feries will be = A $+\frac{n-1}{1}B+\frac{n-1}{1}\times\frac{n-2}{2}C+\frac{n-1}{1}\times\frac{n-2}{2}\times\frac{n-3}{3}$

 $D + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n-3}{3} \times \frac{n-4}{4} E +, &c.$

For from the equations in the last Prop. viz. $\mathbb{R} = b$ -A, C = c - 2b + A, &c. we have, by transposing, b = A + B, = -A + 2b + C = -A + 2A + 2B + C

(expunging b); that is, c = A + 2B + C, d = A - 3b + 3c + D = A - 3A - 3B + 3A + 6B + 3C + D (expunging b and c); that is, d = A + 3B + 3C + D. Also e = -A + 4b - 6c + 4d+E = (expunging b, c, d) - A + 4A + 4B - 6A-12B-0C+4A+12B+12C+4D+E; that is, e = A + 4B + 6C + 4D + E, &c.

Then putting A, b, c, d, &c. for the nth term, and n fucceffively = 1, 2, 3, 4, &c. the feries will be evi-

Cor. 1. If d', d', d''', &c. be the first of the first, se-

cond, third order, &c. of differences; then

The nth term of the series A, b, c, d, &c. will be $= A + \frac{n-1}{1} d' + \frac{n-1}{1} \times \frac{n-2}{2} d' + \frac{n-1}{1} \times \frac{n-2}{2}$ $\times \frac{n-3}{3} d'' + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n-3}{3} \times \frac{n-4}{4} d''' +$

For B = d, C = d'', D = d''', &c. And the co-

efficients are the unciæ of the n-1th power.

Cor. 2. Hence also it follows, that any term of a given feries may be accurately determined, if the differences of any order happen at last to be equal. Cor. 3. Hence

A=A, the first term. b=A+B, the 2d term. c=A+2B+C, the 3d term. d=A+3B+3C+D, the 4th term. e=A+4B+6C+4D+E, the 5th term. f=A+5B+10C+10D+5E+F, the 6th term. g=A+6B+15C+20D+15E+6F+G, the 7th term,

PROP. 3. If a, b, c, d, e, &c. be any feries, and d d", d", &c. the first of the several orders of differences;

The fum of n terms of the feries is = na + n $\times \frac{n-1}{2}d + n \times \frac{n-1}{2} \times \frac{n-2}{3}d' + n \times \frac{n-1}{2} \times \frac{n-2}{3}$

For in the feries of quantities,

If diff. are a, a, a+b, a+b+c, a+b+c+d, &c. 2d diff. a'', a'2, a'3, &c. 3d diff. a'', a''2, &c. 4th diff. a''', &c.

Therefore (by Cor. 1. Prop. II.) the n + 1th term the nth term of the feries, a, a+b, a+b+c, a+b+c+d, &c. is $= o + na + n \times \frac{n-1}{2}d + n \times \frac{n-1}{2}$

 $\times \frac{n-2}{2} d'' + &c.$ But the nth term of the series a, a+b, a+b+c, &c. is the fum of n terms of the feries, a, b, c, d, &c. and therefore equal to $na+n \times$ $\frac{n-1}{2}d' + n \times \frac{n-1}{2} \times \frac{n-2}{3}d' + \&c.$ For a fuller account of this method, and its applica-

tion to curves, we refer the reader to Emerson's works, from which these three propositions are taken.

DIFFRACTION, a term first used by Grimaldi, to denote that property of the rays of light, which others have called inflection; the discovery of which is attributed by fome to Grimaldi, and by others to Dr

DIGGES (Leonard), an eminent mathematician of the 16th century, was descended from an ancient samily, and born at Digges court in the parish of Barham in Kent; but we know not in what year. He was fent to University-college in Oxford, where he laid a good foundation of learning and science; and retiring thence without a degree, profecuted his studies, and composed the following works: 1. " Tectonicum: briefly shewing the exact Measuring and speedy Reckoning of all manner of Lands, Squares, Timber, Stones, Steeples, &c. 1556," 4to. Augmented and published again by his fon Thomas Digges, 1592, 4to, and reprinted in 1647, 4to. 2. "A geometrical practical Treatife, named Pantometria, in three books." This he lest in manuscript; but after his death his son supplied such parts of it as were obscure and imperfect, and published it in 1591, folio; subjoining, "A Discourse geometrical of the five regular and platonical bodies, containing fundry theoretical and practical propolitions, arifing by mutual conference of these solids, inseription, circumscription, and transformation." 3."Prognoffication everlasting of right good Effect: or, Choice Rules to judge the Weather by the Sun, Moon, and Stars, &c." 1555, 1556, and 1564, 4to, corrected and augmented by his fon, with divers general tables, and many compendious rules, 1592, 4to. He died about 1574.

DIGGES (Thomas), only fon of Leonard Digges, after a liberal school education, went and studied for some time at Oxford; and by the improvements which he made there, and the instructions of his learned father, became one of the greatest mathematicians of his age. When Queen Elizabeth fent some forces to astist the oppressed inhabitants of the Netherlands, Digges was appointed multer master-general of them; by which he had an opportunity of becoming skilled in the art of

war. Befides revifing, correcting, and enlarging some pieces of his father's already mentioned, he wrote and published the following learned works himself: namely, 1. " Ala five feals Mathematics; or, Mathematical Wings or Ladders, 1573," 4to. This book contains feveral demonstrations for finding the parallaxes of any comet, or other celestial body, with a correction of the errors in the use of the radius astronomicus. 2. " An arithmetical military Treatife, containing fo much of Arichmetic as is necessary towards military Discipline, 1579," 4to. 3. " A geometrical Treatife, named Stratioticos, requisite for the perfection of soldiers, 1579," 4to. This was begun by his father, but finished by himself. They were both reprinted together in 1590, with several amendments and additions, under this title, " An arithmetical warlike Treatife, named Stratioticos, compendiously teaching the science of numbers, as well in fractions as integers, and fo much of the rules and equations algebraical, and art of numbers coeffical, as are requisite for the profession of a souldier. Together with the moderne militaire discipline, offices, lawes, and orders in every well-governed campe and armie, inviolably to be observed." At the end of this work there are two pieces; the first intitled, " A briefe and true report of the proceedings of the Earle of Leycester, for the reliefe of the towne of Sluce, from his arrival at Vlishing, about the end of June 1587, untill the furrendrie thereof 26 Julii next enfuing. Whereby it shall plainelie appear, his Excellencie was not in anie fault for the loffe of that towne"- The fecond, "A briefe difcourse what orders were best for repulsing of foraine forces, if at any time they should invade us by fear in Kent, or elsewhere." 4. " A perfect description of the celestial orbs, according to the most ancient doctrine of the Pythagoreans, &c." This was placed at the end of his father's "Prognostication everlasting, &c." printed in 1592, 4to. 5. " A humble motive for affociation to maintain the religion established, 1601," 8vo. To which is added, his "Letter to the fame purpose to the Archbishops and Bishops of England." 6. "Eng-land's Defence: or, a Treatise concerning Invasion." This is a tract of the same nature with that printed at the end of his Stratioticos, and called, "A briefe Discourse, &c." It was written in 1599, but not published till 1686. 7. "A Letter printed besore Dr John Dee's Parallatica Commentationis praxeosque nucleus quidam, 1573," 4to. Belides thele and his Nova Corpora, he had by him feveral mathematical treatifes ready for the press; which, by reason of law suits and other avocations, he was hindered from publishing. He died in 1595, but we know not at what age.

DIMINUTION, in music, is the abating fomething

of the full value or quantity of any note.

DIOPHANTUS, a celebrated mathematician of Alexandria, has been reputed to be the inventor of algebra; at least his is the earliest work extant on that science. It is not certain when Diophantus lived. Some have placed him before Christ, and some after, in the reigns of Nero and the Antonines; but all with equal uncertainty. It feems he is the fame Diophantus who wrote the Canon Astronomicus, which Suidas fays was commented on by the celebrated Hypatia, daughter of Theon of Alexandria. His reputation must have been very high among the ancients, fince they ranked him with Pythagoras and Euclid in mathematical

Bell

Dition.

book De Arithmeticis, has collected, from Diophantus's epitaph in the Anthologia, the following circumstances of his life; namely, that he was married when he was 33 years old, and had a fon born five years after; that this fon died when he was 42 years of age, and that his father did not furvive him above four years; from which it appears, that Diophantus was 84 years old when he died.

DIOPTER, or DIOPTRA, the same with the index or alhidade of an astrolabe, or other such instrument.

DIOPTRA was an instrument invented by Hipparchus, which ferved for feveral uses; as, to level water-courses; to take the height of towers, or places at a distance; to determine the places, magnitudes, and distances of the

DIRECT, in arithmetic, is when the proportion of any terms, or quantities, is in the natural or direct order in which they stand; being the opposite to inverse, which confiders the proportion in the inverted order of the terms. So, 3:4::6:8 directly; or 3:4::8:6 inversely.

DIRECTION, in astronomy, the motion and other

phenomena of a planet when direct.

DIRECTION, in aftrology, is a kind of calculus, by which they pretend to find the time in which any notable accident shall befal the person whose horoscope is

DISCRETE QUANTITY, is such as is not continued and joined together. Such, for instance, is any number.

DITTON (Humphry) an eminent mathematician, was born at Salisbury, May 29, 1675. Being an only fon, and his father observing in him an extraordinary good capacity, determined to cultivate it with a good education. For this purpose he placed him in a reputable private academy; upon quitting of which he, at the defire of his father, though against his own inclination, engaged in the profession of divinity, and began to exercise his function at Tunbridge in the county of Kent, where he continued to preach some years; during which time he married a lady of that place.

But a weak constitution, and the death of his father, induced Mr Ditton to quit that profession. And at the perfuasion of Dr Harris and Mr Whiston, both eminent mathematicians, he engaged in the fludy of mathematics; a science to which he had always a strong inclination. In the profecution of this science, he was much encouraged by the success and applause he received: being greatly esteemed by the chief professors of it, and particularly by Sir Isaac Newton, by whose interest and recommendation he was elected master of the new mathematical school in Christ's Hospital; where he continued till his death, which happened in 1715, in the 40th year of his age, much regretted by the philosophical world, who expected many useful and ingenious discoveries from his affiduity, learning, and penetrating genius.

Mr Ditton published several mathematical and other tracts, as below .- 1. Of the Tangents of Curves, &c.

Philos. Trans. vol. 23.

2. A Treatife on Spherical Catoptrics, published in the Philos. Trans. for 1705; from whence it was copied and reprinted in the Acta Eruditorum 1707, and

thematical learning. Bachet, in his notes upon the 5th also in the Memoirs of the Academy of Sciences at Dittor

2. General Laws of Nature and Motion; 8vo, 1705. Wolfius mentions this work, and fays that it illustrates and renders easy the writings of Galileo, Huygens, and the Principia of Newton. It is also noticed by La Roche, in the Memoires de Literature, vol. 8. page

4. An Inflitution of Fluxions, containing the first Principles, Operations, and Applications, of that admirable Method, as invented by Sir Isaac Newton, 8vo, 1706. This work, with additions and alterations, was again published by Mr John Clarke, in the year 1726.

5. În 1709 he published the Synopsis Algebraica of John Alexander, with many additions and corrections.

6. His Treatise on Perspective was published in 1712. In this work he explained the principles of that art mathematically; and befides teaching the methods then generally practifed, gave the first hints of the new method afterwards enlarged upon and improved by Dr Brook Taylor; and which was published in the year

7. In 1714, Mr Ditton published several pieces both theological and mathematical; particularly his Discourse on the Resurrection of Jesus Christ; and The New Law of Fluids, or a Discourse concerning the Ascent of Liquids, in exact Geometrical Figures, between two nearly contiguous Surfaces. To this was annexed a tract, to demonstrate the impossibility of thinking or perception being the refult of any combination of the parts of matter and motion: a subject much agitated about that time. To this work also was added an advertisement from him and Mr Whiston, concerning a method for discovering the longitude, which it seems they had published about half a year before. This attempt probably cost our author his life; for although it was approved and countenanced by Sir Isaac Newton, before it was presented to the Board of Longitude, and the method has been successfully put in practice, in finding the longitude between Paris and Vienna; yet that board then determined against it: so that the disappoint. ment, together with fome public ridicule (particularly in a poem written by Dean Swift), affected his health fo that he died the ensuing year, 1715.

In an account of Mr Ditton, prefixed to the German translation of his Discourse on the Resurrection, it is faid that he had published, in his own name only, another method for finding the longitude; but which Mr Whiston denied. However, Raphael Levi, a learned Jew, who had studied under Leibnitz, informed the German editor, that he well knew that Ditton and Leibnitz had corresponded upon the subject; and that Ditton had fent to Leibnitz a delineation of a machine he had invented for that purpose; which was a piece of mechanism constructed with many wheels like a clock, and which Leibnitz highly approved of for land use; but doubted whether it would answer on ship-board, on

account of the motion of the ship.

DIVING BELL has been already described in the Encyclopædia; but in that work was given no account of its antiquity or its invention. In the works of Aristotle we read of a kind of kettle used by divers to chable them to remain for some time under water; but the manner in which those kettles were employed is not

Don.

clearly described. "The oldest information (fays Profeffor Beckmann) which we have of the use of the divine bell in Europe, is that of John Tailnier, who was born at Hainault in 1509, had a place at court under Charles V. whom he attended on his voyage to Africa. He relates in what manner he faw at Toledo, in the presence of the emperor and several thousand spectators, two Greeks let themselves down under water, in a largeinverted kettle, with a burning light, and rife up again without being wet. It appears that this art was then new to the emperor and the Spaniards, and that the Greeks were caused to make the experiment in order to prove

the poffibility of it."

When the English, in 1588, dispersed the Spanish fleet, called the Invincible Armada, part of the ships went to the bottom, near the ifle of Mull, on the western coast of Scotland; and some of these, according to the account of the Spanish prisoners, contained great riches. This information excited, from time to time, the avarice of speculators, and gave rise to several attempts to procure part of the loft treasure. In the year 1665. a person was so sortunate as to bring up fome cannon, which, however, were not fufficient to defray the expences. Of these attempts, and the kind of diving bell used in them, the reader will find an account in a work printed at Rotterdam in 1669, and entitled G. Sinclari Ars nova et magna gravitatis et levitalis. In the year 1680, William Phipps, a native of America, formed a project for fearching and unloading a rich Spanish ship sunk on the coast of Hispaniola; and reprefented his plan in fuch a plaufible manner, that King Charles II. gave him a ship, and furnished him with every thing necessary for the undertaking. He fet fail in the year 1683; but being unsuccessful, returned again in great poverty, though with a firm conviction of the possibility of his scheme. By a subscription promoted chiefly by the Duke of Albemarle, the fon of the celebrated Monk, Phipps was enabled, in 1687, to try his fortune once more, having previously engaged to divide the profit according to the twenty shares of which the subscription consisted. At first all lis labour proved fruitless; but at last, when his patience was almost entirely exhausted, he was to lucky as to bring up, from the depth of fix or feven fathoms, fo much treasure that he returned to England with the value of two hundred thousand pounds sterling. Of this fum he himself got about fixteen, others fay twenty, thousand, and the duke ninety thousand pounds. After he came back, some persons endeavoured to perfuade the king to feize both the flip and the cargo, under a pretence that Phipps, when he folicited for his majesty's permission, had not given accurate information respecting the business. But the king answered, with much greatness of mind, that he knew Phipps to be an honest man, and that he and his friends should share the whole among them had lic returned with double the value. His majesty even conferred upon him the honour of knighthood, to shew how much he was satisfied with his conduct. We know not the construction of Phipps's apparatus; but of the old figures of a diving machine, that which approaches nearest to the diving. bell is in a book on fortification by Lorini; who defcribes a square box bound round with iron, which is the diver. This ingenious contrivance appears, how- out through the port-holes, or the windows, whatever

ever, to be older than that Italian; at least he does not Dodecate. pretend to be the inventor of it.

In the year 1617, Francis Kessler gave a description of his water armour, intended also for diving, but which cannot really be used for that purpose. In the year 1671, Witlen taught, in a better manner than any of his predecessors, the construction and use of the divingbell; but he is much mistaken when he says that it was invented at Amsterdam. In 1679 appeared, for the first time, Borelli's well known work de motu animalium, in which he not only described the diving bell, but also proposed another, the impracticability of which was shewn by James Bernoulli. When Sturm published his Collegium curiosum in 1678, he proposed some hints for the improvement of this machine, on which remarks were made in the Journal des squans. To him succeeded Dr Halley, whose bell is well known.

DODECATEMORY, the 12 houses or parts of the zodiac of the primum mobile. Also the 12 signs of the zodiac are fometimes fo called, because they con-

tain each the 12th part of the zodiac.

DOME. See ARCH in this Supplement.

DOMINGO, or ST DOMINGO. See HISPANIOLA,

both in Encycl. and in this Supplement.

DON MARTIN DE MAYORGA, the name given by the Spaniards to a cluster of islands in the South Sea, discovered on the 27th of February 1781 by Don F. A. Maurelle, a celebrated pilot of that nation.

Those islands are described by him as abounding with tropical fruits and roots, as liighly cultivated, and as inhabited by a people confiderably polished. The fertility of the land, fays he, is fuch, that its cultivation cannot fail to promife a favourable harvest. Every where are feen an endless number of cocoa-nut trees, beautiful banana trees ranged in lines with the greatest order, and numerous plantations of potatoes, of which he describes some as fifteen feet in length, and of the thickness of a man's thigh. He admired the order with which every thing was disposed. No weeds were suffered to grow between the plants; and their roads were kept in repair with a diligence deferving imitation bythe most civilized nations.

Their government appears from his account to be despotic. The sovereign, who is called the Tubou, is held in the highest veneration by his subjects, whose lives and properties are at his disposal. Under him there is an order of nobles called Equis, who, though they shrink into infignificance in the presence of the Tubou, have great authority over the people. These people are said by Maurelle to be of great muscular strength and large stature, the ordinary height of the men being fix feet or fix feet four inches, while many of them are much taller. It would appear, too, that they delight in gymnastic exercises; for when the Tubou, by whom he had been treated with great hospitality, wished to amuse him and his ship's company, he exhibited to them feats of wreftling and boxing, and that as well by the women as by the men.

Though these people put the greatest considence in the Spaniards, and frequently staid whole nights on board the frigate, they had yet the common inclination of favages to steal. " Every time they came on board (fays our author), clothes, iron-work, whatever fell in furnished with windows, and has a stool affixed to it for their way, they considered as lawful prize. They drew

Draccana, was within their reach. They thieved even to the very chain of the rudder. I made my complaints to the king; he gave me permission to kill whomsoever I should detect in the act; and I was affured he had himfelf difcovered and punished with death the authors of the complained of theft. Our vigilance was necessarily called into action; we surprised the islanders striving to tear away the new rudder chains; we fired a pistol at them, one of them fell dead on the occasion, and this was an awful lesson for those who were either on board or alongfide of the frigate; they faid to themselves, or to one another, chito (robber) fama (death)."

They make of the bark of trees a kind of cloth not unlike that which has been brought from other illands in the South Sea; and our author describes the women as being peculiarly neat both in their dress and in They had their mantles or loole gartheir persons. ments adjusted in next plaits and folds, and becomingly attached by a knot over the left shoulder. They wore garlands or wreaths on the head, and chaplets of large glass beads round their necks; the hair was pleasingly disposed in tresses, and the whole person persumed with an oil of an agreeable odour; above all, the skin was so exquifitely clean, that they would not have tuffered the smallest particle of dust to remain upon it a moment.

In this archipelago Don Maurelle found a safe harbour, to which he gave the name of El Refugio; and which he places in South Lat. 18°. 36'. and W. Lon.

177°. 47'. 45". of Greenwich.
DRACCENA DRACO (fee DRACOENA, Encycl.), is a native of Madeira, though it is there becoming scarce. The following account of it is by La Martiniere, naturalist in the last voyage of discovery by La Perouse. "The idea of the draccena draco (fays he) given by the shabby specimens cultivated in our hot-houses, is far inferior to that we entertain of it when we have an opportunity of feeing it in its native foil. I met with three in particular, of which the trunk was fix or feven feet high, and four and a half, or five in diameter. The principal branches, 12 or 15 in number, and as thick as a man's body, shoot out a little obliquely, dividing themselves generally into two, and now and then into three, to the height of 40 or 50 feet, including the seven feet of the trunk. The leaves are all at the extremity of the branches, where they are placed in alternate order, and form a cluster. This tree prefents the most perfect regularity to the eye, and tempts the spectator to think, that the most skilful gardener makes it the object of his daily care."

DRAINS. Under this word in the Encyclopædia we published Mr Bayley of Hope's method of draining land; and by a letter from the author, we have fince learned, that experience, the best guide, has fully proved the usefulness and durability of his drains. With a candour, however, worthy of a man who writes not for fame, but for the good of the public, he informs us of a mistake into which he had led us; and requests us to

correct it in this Supplement.

"I wish (says he) that, in the Supplement to the Encyclopædia, due notice may be taken of a very great error into which I was led in my scheme of making the main drains. I conjectured, that where the bottom of the trench was of a hard or folid body, as clay or marl, it might not be necessary to lay it with bricks or stones; but in this I was quite wrong. By the runs of water, the alternate changes from wet to dry, and the access

of air, these hard bottoms have been rendered friable; Drain they have crumbled away, and let in all my drains' which were not supported by a bottom laid with brick or stone." For this information we request the author to accept of our thanks, and we are perfuaded we may

add, the thanks of the public.

As the draining of land is a matter of great importance in agriculture, and as the subject has been again brought before us, we imagine that our agricultural readers will be glad to find here the substance of a paper on this subject, for which the author received the filver medal of the Society instituted for the encouragement of ARTS, MANUFACTURES, and COMMERCE. That author is Mr John Wedge of Bickenhill, near Coventry, who is not only a great farmer himself, but had likewife been employed by the Earl of Alesford in the management of several estates. Encouraged by his lordship's liberality, Mr Wedge informs the society, that he had been employed for some years in draining large portions of land, of which part was in the Earl's occupation, and part in his own, as tenant to his lordship. The principles upon which he proceeded, as well as his mode of procedure, he states in the following terms:

In every country there are large portions of land that, in wet feafons, have always what may be called a dry furface, and other portions of land that have always a moist or wet surface; the former of these admitting all the water which falls upon them to fink freely through their pores to various depths, till falling on clay, or some other unctuous earth, whose pores will not permit it to pass through, it is there held up to a height proportioned to the quantity of water which comes upon it, and the facility with which that water is discharged. Thus, held up to various heights, it ferves as a fountain to distribute its water (either by veins of fand, pebbles, or rock), according to the formation of the different under strata on the neighbouring lands, and there forms bogs and other varieties of wet furface, on a basis that will be always found to consist of marl, or clay, or some mixture thereof. The effect of water thus distributed may be divided into two classes. The first class, where the water is thrown out by a body of marl or clay, &c. upon the furface of descending ground, and in the valley (there held up by clay also) forms bogs or swamps. The second class, where the water is held up by marl or clay, as before, having above that marl or clay a stratum of sand, or pebbles, through which the water passes; and above those sands or pebbles another stratum of marl or clay, through the weakest parts of which the water, by a continual pressure from its fountain, forces a passage upwards; and thus, through the weakest parts of the marl or clay, furnishes a continual supply of water on the surface, for the formation or growth of bogs, &c. in proportion as this water is more or less abundantly supplied by its fountain or head, namely, the higher lands, into which rain-water freely passes, as before described. There are also different soils, under different circumstances, which may form a third class of land for draining; fuch as, strong deep soils, or open light soils, having near the furface a body of marl or clay. In either of these cases, the water which falls on the surface must, for reasons which are self-evident, keep such lands, in rainy seasons, constantly wet and cold; and it should be observed, that a mixture of all the three before-described classes of wet land sometimes occur in one field, by sudden alterations of the under strata, and thereby perplex the operator, by requiring all the different modes of

draining in the fame field.

If it be admitted that bogs are thus formed and fed, their cure may be effected with certainty. The first class, by cutting through the stratum (be it sand, pebbles, or rock,) that conveys the water to the bog, and carrying off that water by a close drain to some proper place, where the level admits of its discharge. cond class, by finking a drain to any convenient depth in the upper clay; and then digging or boring with a large auger, at a small distance on one side of this drain, through the remaining part, be it (the upper clay) ever so deep, into the under stratum of fand, pebbles, or rock, through which the water passes; which will then rush up into the drain so made, with a velocity proportioned to the height of the land or fountain whence it is supplied. As this drain advances through the land, holes must be dug or bored, as before, every feven yards, or at fuch distance as the strength of the fprings may require; and the whole of the water thus brought up by tapping the springs, is carried off by the drain made in the upper clay, which must be a close one, to its proper level, and there discharged.

By both these methods of draining, large tracts of land, under favourable circumftances, may be cured with one drain. The best place for fixing these drains is where the fratum that conveys the water comes nearest to the furface; and the best method of ascertaining that, is to bore or dig in different parts through the diffe-

rent under strata.

The third class may be easily cured by close drains, at fuch diffances and depths as will best carry off the furface-water. It may not be improper to observe, that where the different strata or measures crop out, that is, become gradually more and more shallow in some certain direction (as is often the case, till, one after the other, they all present themselves in succession on the furface of the earth), draining may often be much more eafily and better effected by croffing with the drain the different strata or measures where the levels and other circumstances will admit.

Some of the land drained was part of a common, in the parish of Church Bickenhill, in the county of Warwick; part of it was covered with moss and ling, had a peaty furface about fix inches deep, and produced little or no grafs: in all wet seasons it was filled quite to the furface, and often overflowed, with water. Some of the land was much more unfound, deeper of peat, and covered with mofs, in most parts nine inches long;

another part was an absolute bog in all seasons.

Having dug or bored with a large auger into feveral parts of the land, Mr Wedge found peat, gravel, and fand mixed, and a quick-fand almost uniformly. The quick-fand in every part, after getting an inch or two into it, seemed almost as sluid as water. Judging from this, that no materials for a drain could be laid in the quick-fand, but what it would immediately bury, he dug a trench almost to the quick fand, leaving gravel, &c. of fufficient strength to bear up the materials for a hollow drain; these materials were two sides and a coverer of stone, with a peat-turf on the top to keep out the foil. At every seven yards forward, by the fide of this drain, he dug a hole in the quick-fand as deep as it would permit. From these holes the water rose tree-

SUPPL. VOL. I. Part II.

ly into the hollow drain, and was by it discharged at a Drains. proper level. It may be proper to remark, that the stone made use of for this drain, and all others here mentioned, was a red fand and rag-stone, which easily split into proper fizes for the purpose, and is very durable; it cost about sixpence per ton getting, exclusive of carriage. The drain thus formed ran on the whole rather freely, and made the land dry for a few yards on each fide thereof, but was far from having the effect he improperly expected; for it evidently appears that the drain could only take a very small portion of the water from fo large a quick-fand, which it did not penetrate more than two inches; and that it could drain only to its own depth, or, at most, to that depth in the fountain which supplied the quick-fand. His purpose was then defeated; and his motive for mentioning this error can-

not, he hopes, be mistaken.

He now did what he fays he ought to have done before, that is, examined the different strata to a greater depth, particularly on the bog, and at the upper edges thereof, and found the bog to be what has been described under the first class. He therefore determined to attempt the cure in the manner before prescribed for that class, namely, to cut through the whole of the stratum (in this instance, of quick fand), through which he found the water pass. This he effected as follows: The summer being dry, and favourable for the purpose, and having previously made his main open drain, he began his main close drain the first week in June 1791, three feet wide, on the declivity near the edge of the great bog. In the first operation he dug through the peat, the hard fand, and gravel, and one spade's graft (about nine inches deep, and feven inches wide) into the quickfand the whole length of this drain, which was 73 perches, of eight yards to the perch, in length. The drain thus dug ran copiously, not less than 60 gallons per minute. In this state he left it about nine days: the effect of it was rapid, both above the drain and on the bog below. Upon examination, he now found about three inches on the top of the spade's graft, which had been made into the quick fand, perfectly dry. He then dug out these three inches of dry sand, to nearly the whole width of the drain, three feet; and at the same time dug out, as before, another spade's graft from the top of the quick-fand, as near the middle of the drain as possible. This was left to run a few days, as before, and had the same effect, namely, three or four inches more of the top of the quick-fand became dry and hard. The same operation was repeated again and again with the same effect, till the purpose of getting through this quick-fand was completed, so far at least as the level of the main open drain would permit. The stream of water continued increasing during the whole operation; the bog below the drain was quite dry, and the land above perfectly fo. The drain which was first made. and continued running for fome time during the progress of the main close drain, became gradually dry; and has not, fince that drain was finished, discharged one fingle drop of water. Great care was necessary, in making the main close drain, to keep the stream of water in the middle of it, otherwise the current would have undermined the fides, as it sometimes had done, and caused them to fall in. For this reason it was necesfary, when the dry fand was taken from the top of the quick-fand, immediately to take out a spade's graft from Drains. the middle thereof, in order to divert the current from

The main close drain thus made was three feet wide at top, about nine feet deep on the average, and, bevelling a little from the top, it was about one foot ten inches wide at the bottom. The ftone and other materials were put into this drain in the following manner:

Where the drain went through the quick fand into the stratum of clay below it, as in most places it did, the bottom, and in some instances the sides, wanted no particular fecurity (A); but where it did not go quite through the quick fand, which the level of his main open drain in some places would not admit, the bottom of the drain was covered half an inch thick with ling; then peat-turfs, one foot wide and three or four inches thick, were cut in convenient lengths, and placed on their edges on each fide of the bottom of the drain, forming two fides of a trough of peat; then fide stones about eight inches high, and a stone coverer, were put in upon the ling between the peat turfs; a large peatturf, near two feet wide and four inches thick, was then cut and firmly placed over the whole: this left in the bottom of the drain an open space, of more than fix inches square, for the water to pass. The whole was then completed by filling in the upper part of the

In this way the author drained, for about L. 80, thirty acres of land, which, from being of no value whatever, became worth at least 14 shillings per acre of yearly rent. He likewise hollow-drained nine acres by the method prescribed for the third class of wet land. These drains were made a few yards below that part of each field where the dry and wet land separate, about 22 inches deep, with fides and a coverer of stone, and ling on the top of it, to keep the earth from running in. The length of these drains was 880 yards, and the expence of labour and materials three halfpence per yard. The drains, in wet weather, discharge a large quantity of water; and will, he has no doubt, answer the intended purpose. Thus far relates to land in his own occupation.

Nine acres of the land in the earl of Aylesford's occupation was almost an entire pulp. This bog was of the fecond class, namely, water passing through a quickfand, and confined by a stratum of clay below, and another stratum of clay above it. The water thus confined, being pressed by its fountain, and forced up thro' the weakest parts of the clay, had formed a bog of irregular thickness on the surface, in some places fix feet deep, in others not more than two. As there is a confiderable fall in this land from east to west, he thought it expedient to put two drains into it; and this appears to him to have been necessary, from a consideration that both these drains continue to run in the same proportions as when first opened. The manner in which these drains were executed was, by digging through the different upper strata, and as deep into the clay as the main open drain would admit; then digging or boring through the remaining part of that clay into the quickfand, at the distance of about fix yards, in a progressive

manner.

The water rifing rapidly through these holes into the Drain close drains, has effected a complete cure of this land, every part of which will now bear a horse to gallon upon it. These drains discharge 3660 gallons an hour; which is much less than they did at first, as must be the case in all bogs. This land will be worth twenty shillings per acre. The draining cost twenty five pounds; and the length of the under-ground drains is eight lundred and fourteen yards.

Mr Wedge had just finished (January 1792) draining another piece of land, about forty-three acres. As this was intended to answer two purposes, one, to drain the land, the other, to give an additional supply of water to a mill pool, and as a circumstance arose in the execution of the work which frequently happens in draining land, namely, a fudden alteration in the pofition of the under strata-a description thereof will not, we hope, be thought tedious. This draining was begun at the level of a mill pool, and continued, without any great difficulty, to the distance of about thirtytwo chains, in the manner before described as a cure for the fecond class of boggy land: but at or near that place the under strata altered their position; the quickfand which conveyed the water now became of twice its former thickness; and the clay, which had hitherto been above that quick-sand, for some distance disappeared. From the quick fand thus becoming fo much deeper, he could not, with the level of the mill-pool, cut through it; nor indeed, from the wetness of the feason, would such an operation have been proper. He therefore continued a shallow drain to some distance, making fide-holes into the quick-fand, which ran freely; but as this could not cure the whole of the bog below, he branched out another drain (which was made by the method described for curing the second class of wet or boggy land), by finking a close drain through the upper strata into the upper clay, and then, at a small distance on one fide of this close drain, boring a hole with an auger through the remaining part of that clay into the quick-fand; and at every eight yards, as this close drain advanced, still boring other holes, in the manner before described: through many of these holes the water rushed with great rapidity. I'he water discharged by these drains into the mill-pool is 168 gallons per minute, or 3780 hogsheads in a day; which is after the rate of 1,379,700 hogsheads in a year.

About fix acres of this land were always found; about twelve acres on the north fide were an absolute pulp, and the remaining twenty fix acres very unfound. The whole is now found, and will when cultivated be worth fixteen shillings per acre. This land would have been drained at a much less expence into the main open drain; but then the water, which was much wanted for the mill, would have been loft. These close drains are in length 1452 yards, and cost I. 100, of which about L. 30 ought to be charged to the mill.

Important as this subject is, we must not enlarge this article, or we should make large extracts from Dr Anderson's Prastical Treatise on Draining Bogs and Swampy Grounds, lately published. It is proper, however, to inform the public, that the author puts in his claim

(A) He will probably find in time that he was under the fame miltake with Mr Bayley, and we hope that with Mr Bayley's candour he will acknowledge it.

ffers for being the first discoverer of that mode of draining for which Mr Elkington has obtained from parliament a premium of L. 1000; and the reader who shall turn to the article DRAINS in the Encyclopædia, will per-

ceive that his claim is well-founded. DROSSERA ANGLICANA, or the SUNDEW (fee DROSSERA, Encycl.), is a very minute villous plant, usually growing entangled with moss on peat bogs; the leaves are curiously fringed with numerous strong reddish hairs, terminated by small pellucid globules of viscous liquor, which occasion, by the reflection of the Sun, that peculiar lustre from which its name is derived. It is in these hairs that the effential properties of the plant reside; for if a small insect should fix itself on one of the leaves, these hairs immediately begin to close, one by one, till the infect is wholly environed by them, and then the leaf in which it is imprisoned gradually bends inwards, fo as to reach the base: in this state the infect is killed by the operation of the acrimonious juice exuding from the ends of the hairs. Rothius (as quoted by Withering, in his Arrangement of British Plants,) mentions the effects of this singular plant, occasioned by the irritation of an ant, which he placed on the centre of one of the leaves with a pair of pincers. The ant, in endeavouring to escape, was held fast by the vifcous juice of the fmaller hairs till the large ones, together with the edges of the leaf, closed in and imprisoned it. The ant died in fifteen minutes; but he observes, that the effects followed fooner or later, in different experiments, according to the state of the weather. Dr Withering has published a similar account of the fensitive properties of the fundew, which was communicated to him by two of his botanical friends, and which he has made very entertaining and interesting. The same thing is confirmed by a writer in the Monthly Magazine for August 1797; who fays, that whenever he made experiments on the droffera with ants and other diminutive infects, he commonly found them perifh in a shorter time than sifteen minutes. His experiments were made on the drossera rotundisolia. Rothius, however, observes, that the longifolia produces the same effects, but with greater rapidity. In concluding his account, Dr Withering fuggests this enquiry: "Whether this destruction of infects be not necessary to the welfarc

DRUGS (fee Encycl.) are fo commonly counterfeited, or at least adulterated, that, in London, the royal college of physicians, it is well known, has long ago appointed a court of examiners to investigate the goodness of drugs and medicines in the different chemists and apothecaries shops. The counterfeit, however, is made up with fuch dexterity, that not only the merchant and drug-broker, but even the man of skill is fometimes deceived; and indeed nothing can detect this imposition but a practical knowledge of chemistry. We therefore recommend it to every father of a family to fludy our Supplementary article CHEMISTRY with this view, if with no other; for whatever be the faults of that article, we have lost much labour if it be not fufficiently perspicuous to enable every man, not an abfolute stranger to physical science in all its branches, to detect the common impostures of drug-sellers.

of the plant?" And it is furely worth fome botanist's

while to take fome pains to answer the question.

DUFTER, in Bengal, an office or department.

DUFTER Cana, the place where the office is kept.

DWARFING of Vegetables, an art invented by Dwarfing, the Chinese, to which the attention of Sir George Dyeing. Staunton was attracted on the following occasion:

When the embaffy was at Chusan (See Chusan in this Supplement), the gentlemen who went on shore were introduced to the governor in his hall of audience, where on feveral tables were placed, in frames filled with earth, dwarf pines, oaks, and orange trees, bearing fruit. None of them exceeded in height two feet. Some of those dwarfs bore all the marks of decay from age: and upon the furface of the foil were interspersed small heaps of stones, which, in proportion to the adjoining dwarfs, might be termed rocks. These were honey-combed and moss-grown, as if untouched for ages, which ferved to maintain the illusion, and to give an antique appearance to the whole. This kind of flunted vegetation feemed to be much relished by the curious in China; and specimens of it were to be found in every confiderable dwelling. To produce them formed a part of the gardener's skill, and was an art invented in that country. Beside the mere merit of overcoming a difficulty, it had that of introducing vegetables into common apartments, from which their natural fize

must otherwise have excluded them.

The general method of obtaining vegetable dwarfs is faid to be the following: A quantity of clay or mould is applied to the upper part of the trunk of a tree, from which a dwarf is intended to be taken and close to its division into branches. The mold is to be confined to the fpot by coarfe hempen or cotton cloth, and to be carefully kept moist by water. In consequence of this application, continued fometimes above a twelvemonth, fmall tender fibres shoot down like roots from the wood into the mould. The part of the trunk emitting those new fibres, together with the branch rifing immediately above it, is then to be carefully separated from the rest of the tree, and planted in new earth, in which the fibres become new roots, while the former branch is now the stem of the vegetable thus transformed in some measure. This operation does not destroy or alter the productive faculty which those parts enjoyed before their separation from their parent root. That which, while a branch of the original tree, bore flowers and fruit, continues to produce the fame, though no longer supported upon any stock. The terminal buds of such branches of trees as are meant to become dwarfs are torn off; which circumstance prevents the further elongation of those branches, and forces other buds and branchlets from the fides. These branchlets are bent by wires to whatever form the operator wishes: and when the appearance of age and decay is meant to be given to a dwarf tree, it is repeatedly fmeared with treacle or molasses, which attracts multitudes of ants, who, in purfuit of those fweet juices, attack the bark, and, by a gradual corrosion of it, produce the desired effect. These different processes are sometimes attempted to be kept fecret by the gardeners, and they vary defignedly in the mode of carrying them on; but the principle on which they are founded is fufficiently apparent from what is related here; and the contrivance argues ingenuity and perseverance, rather than the practice does true tafte, which confifts in affifting nature in its most favourite works-not in counteracting its operations or difforting its productions.

DYEING is an art, into which, fince the article in 3 R 2

Dycing, the Encyclopædia was published, improvements have rous presses can no longer stand unemployed. It is for- Dycing. been introduced of fuch importance, that it would be unpardonable not to notice them in this Supplement. We accordingly agreed for a new article with a teacher of chemistry, strongly recommended to us as a man who had long directed his attention to that subject; and he folemnly engaged to have the article ready for the prefs before the 1st of November 1798. It is now the 20th of February 1799; and after amufing us from week to week, and from day to day, till our patience is quite exhausted, he finds himself unable (for we will not attribute his conduct to a worse motive) to fulfil his engagement. In this state of things what are we to do? The subject must not be relinquished, and our nume-

tunate that, by following the arrangement of Chaptal, fo well known for the clearness of his method, we have yet an opportunity of treating of dyeing under the article Animal and Vegetable Substances referred to from CHEMISTRY. Such of our readers as are acquainted with the business of the press, will deem this short narrative a sufficient apology for our conduct; and even those of them who are in a great measure strangers to that bufiness, will not think us, circumstanced as we are, deferving of much centure for delaying a fubject, which we pledge ourfelves not to omit under the article to which we have referred.

DYNAMICS.

Definition.

HIS name marks that department of physicomathematical science which contains the abiliract doctrine of moving forces; that is, whatever necesfarily refults from the relations of our ideas of motion, and of the immediate causes of its production and

changes.

Object of dynamics is call its mo-Sicn.

relation.

What.

All changes of motion are confidered by us as the indications, the characteristics, and the measures of chanthat condi- ging causes. This is a physical law of human thought, and therefore a principle to which we may refer, and from which we must devive all our knowledge of those causes. When we appeal to our own thoughts or feelings, we do not find in ourselves any disposition to refer mere existence to any cause, although the beginning of existence certainly produces this reference in an inflant. Had we always observed the universe in motion, it does not appear that we should have ascribed it to a caufe, till the observation of relative rest, or fomething leading to it, had enabled us to separate, by abfiraction, the notion of matter from that of motion. We might then perceive, that rest is not incompatible with matter; and we might even observe, by means of relative motions, that absolute rest might be produced by the concourse of equal and opposite motions. But all this requires reflection and reasoning; whereas we are now speaking of the first suggestions of our minds.

We cannot have any notion of motion in abstracto, without confidering it as a flate or condition of existence, which would remain, if not changed by some cause. It is from changes alone, therefore, that we infer any agency in nature; and it is in these that we are to find

all that we know of their causes.

When we look around us, we cannot but observe, Mechanical that the motions of bodies have, in most cases, if not always, some relation to the fituation, the distance, and the discriminating qualities of other bodies. 'The motions of the moon have a palpable relation to the earth; the motions of the tides have as evident a relation to the moon; the motions of a piece of iron have a palpable dependence on a magnet. The vicinity of the one feems to be the occasion, at least, of the motions of the other. The causes of these motions have an evident connection with or dependence on the other body. We are even disposed to imagine, that they are inherent in that body, and that it possesses certain qualities which

are the causes of those modifications of motion in other

bodies. These serve to distinguish some bodies from others, and may therefore be called PROPERTIES; and, fince the condition of other bodies fo evidently depends on them, these properties express very interesting relations of bodies, and are chiefly attended to in the enumeration of the circumstances which afcertain what we call the nature of any thing. We do not mean to fay, that these inferences are always just; nay, we know that many of them are ill-founded: but they are real, and they ferve abundantly for informing us what we may expect from any proposed fituation of things. It is enough for us to know, that when a piece of iron is so and so situated in relation to a magnet, it will move in a certain manner.

This mutual relation of bodies is differently confidered, according to the interest that we chance to take in the phenomenon. The cause of the approach of the iron to a magnet is generally ascribed to the magnet, which is faid to attract the iron, because we commonly employ the magnet in order that these motions may take place. The fimilar approach of a stone to the earth is ascribed to the stone, and we say that it tends to the earth. In all probability, the procedure of nature is the same in both; for they are-observed, in every instance, to be mutual between the related bodies. As iron approaches a magnet, fo the magnet approaches the iron. The fame thing is observed in the motions of electrified bodies; also in the case of the stone and the earth. Therefore the cause of the motions may be conceived as inherent in either, or in both.

The qualities thus inherent in bodies, constituting Force and their mechanical relations, have been called the MECHA- Adion as NICAL AFFECTIONS OF MATTER. But they are more figurative commonly named POWERS or FORCES; and the event terms which indicates their angle in which indicates their presence, is confidered as the ef chanism feet and mark of their agency. The magnet is faid to ACT on the iron, the earth is faid to ACT on the stone; and the iron and the stone are faid to ACT on the mag-

net and on the earth.

All this is figurative or metaphorical language. All languages have begun with focial union, and have improved along with it. The first collections of words expressed the most familiar and the most interesting notions. In the process of social improvement, the number of words did not increase in the same proportion with the notions that became interesting and familiar in

their

their turn : for it often happened that relations of certain ideas so much refembled the relations of certain other ideas, that the word expressing one of them served very well for expressing the other; because the dissimilar circumstances of the two cases prevented all chance of mistake. Thus we are said to furmount a difficulty, without attaching to the word the notion of getting over a fleep hill. Languages are thus filled with figurative

expressions.

POWER, FORCE, and ACTION, are words which must have appeared in the language of the most simple peon the ple; because the notions of personal ability, strength, and exertion, are at once the most familiar and the most interesting that can have a place in the human mind. These terms, when used in their pure, primitive sense, express the notions of the power, force, and action of a fentient, active, being. Such a being only is an agent. The exertion of his power or force is (exclufively) action: But the relation of cause and effect so much refembles in its refults the relation between this force and the work performed, that the fame term may be very intelligibly employed for both. Perhaps the only case of pure unfigurative action is that of the mind on the body. But as this is always with the design of producing some change on external bodies, we think only of them; the instrument or tool is overlooked, and we fay that we act on the external body. Our real action therefore is but the first movement in a long train of fucceffive events, and is but the remote cause of the interesting event. The resemblance to fuch actions is very throng indeed in many cases of mechanical phenomena. A man throws a ball by the motion of his arm. A spring impels a ball in the same manner by unbending. These two events resemble each other in every circumstance but the action of the mind on the corporeal organ—the rest of it is a train of pure mechanilm. In general, because the ultimate refults of the mutual influence of bodies on each other greatly refemble the ultimate refults of our actions on bodies, we have not invented appropriated terms, but have contented ourselves with those already employed for expressing our own actions, the exertions of our own powers or forces. The relation of physical cause and effect is expressed metaphorically in the words which belong properly to the relation of agent and action. This has been attended by the usual consequences of poverty of language, namely, ambiguity, and fometimes mistake, both in our reflections (which are generally carried on by mental discourse), our reasonings, and our conclusions. It is necessary to be on our guard against such mistakes; for they frequently amount to the confounding of things totally different. Many philosophers of great reputation, on no better foundation than this metaphorical language, have confounded the relations of activity and of causation, and even denied that there is any difference; and they have affirmed, that there is the fame invariable relation between the determinations of the will and the inducements that prompt them, as there is between any physical power and its effect. Others have maintained, that the first mover in the mechanical operations, and indeed through the whole train of any complicated event, is a percipient and intending principle in the fame manner as in our actions. According to these philosophers, a particle of gravitating matter perceives its relation to every other particle in the universe, and determines its own motion according to fixed laws, in exact conformity to its fituation. But the language, and even the actions of all men, they that they have a notion of the relation of an agent to the action, eafily diftinguishable (because all diftinguish it) from the relation between the physical cause and its effect. The proofs of this fact have been adduced in other parts of the Encyclopædia Britannica, as, for example, in the article Philosophy, nº 42. and in this Supplement in the article Action.

These remarks are not made in this place for any philological purpose, such as the mere improvement of language; but because this metaphorical language has affected the doctrines of mechanical philosophy, and has produced a dispute about some of its first principles; and because we find, that the only way to decide this dispute is to avoid, most scrupulously, all metaphorical language, though at the expence of much circum-

When we speak of powers or forces as residing in a Directions body, and the effect as produced by their exertion, the for the fafe body, confidered as possessing the power, is said to acremploy-on the other. A magnet is said to act on a piece of ment of this iron; a billiard ball in motion is faid to act on one analogy. that is hit by it: but if we attempt to fix our attention on this action, as distinct both from the agent and the thing acted on, we find no object of contemplation - the exertion or procedure of nature in producing the effect does not come under our view. When we speak of the action as diffinct from the agent, we find that it is not the action, properly speaking, but the act, that we speak of. In like manner, the action of a mechanical power can be conceived only in the effect produced.

A man is not faid to act unless he produces some Action ineffect. Thought is the act of the thinking principle; plies motion of the limb is the act of the mind on it. In change; mechanics, also, there is action only in so far as there and mere is mechanical effect produced. I must act violently in not actions order to begin motion on a slide: I must exert force, and this force exerted produces motion. I conceive the production of motion, in all cases, as the exertion of force; but it requires no exertion to continue the motion along the flide; I am conscious of none, therefore I ought to infer that no force is necessary for the continuation of any motion. The continuation of motion is not the production of any new effect, but the permanency of an effect already produced. We in-deed consider motion as the effect of an action; but there would be no effect if the body were not moving. Motion is not the action, but the effect of the action.

Mechanical actions have been usually classed under Pression, into two heads: they are either Pressures or Impulsions. They are generally confidered as of different kinds; the exertions of different powers. PRESSURE is supposed to differ essentially from IMPULSE.

Instead of attempting to define, or describe, these two kinds of forces and-actions, we shall just mention some instances. This will give us all the knowledge of their distinctions that we can acquire.

When a ball lies on a table, and I prefs it gently on Examples one fide, it moves toward the other fide of the table of preffions If I follow it with my finger, continuing my pressure, it accelerates continually in its motion. In like manner, when I press on the handle of a common kitchen

jack, the fly begins to move. If I continue to urge or fected by fome other force. It is also remarked, that press round the liandle, the fly accelerates continually, and may be brought into a state of very rapid motion. These motions are the effects of genuine pressure. The ball would be urged along the table in the same manner, and with a motion continually accelerated, by the unbending of a spring. Also, a spring coiled up round the axis of the handle of the jack would, by uncoiling itself, urge round the fly with a motion accelerating in the same way. The more I reflect on the pressure of my finger on the ball, and compare it with the effect of the spring on it, the more clearly do I see the perfect fimilarity; and I call these influences, exertions, or actions, by one name, PRESSURE, taken from the most familiar instance of them.

Again, the very fame motion may be produced in the ball or fly, by pulling the ball or the machine by means of a thread, to which a weight is suspended both are motions accelerated in the fame manner, I call the influence or action of the thread on the ball or machine by the fame name PRESSURE, and WEIGHT is confidered as a pressing power. Indeed I feel the same compression from the real pressure of a man on my shoulders that I would feel from a load laid on them. But the weight in our example is acting by the intervention of the thread. By its preffure, it is pulling at that part of the thread to which it is fastened; this part is pulling at the next by means of the force of coheĥon; and this pulls at a third, and fo on, till the most remote pulls at the ball or the machine. Thus may elasticity, weight, cohesion, and other forces, perform the office of a genuine power; and fince their refult is always a motion beginning from nothing, and accelerating by perceptible degrees to any velocity, this refemblance makes us call them by one familiar name.

But farther, I fee that if the thread be cut, the weight will fall with an accelerated motion, which will increase to any degree, if the fall be great enough. I ascribe this also to a pressing power acting on the weight. Nay, after a very little resinement, I consider this power as the cause of the body's weight; which word is but a distinguishing name for this particular instance of pressing power. Gravitation is therefore added to the lift of pressures; and, for similar reasons, the attractions and repulsions of magnets or electric bodies may be added to the lift; for they produce actual compressions of bodies placed between them, and they produce motions gradually accelerated, precifely as gravitation does. Therefore all these powers may be distinguished by this descriptive name pressures, which, in strict language, belongs to one of them only.

Several writers, however, fubdivide this great class into pressions and solicitations. Gravity is a solicitation ab extra, by which a body is urged downward. In like manner, the forces of magnetifm and electricity, as pressions, and a vast variety of other attractions and repulsions, are called folicitations. We see little use for this distinction, and the term is too like an affection of mind.

IMPULSION is exhibited when a ball in motion puts another ball into motion by hitting, or (to speak metaphorically) by striking it. The appearances, here are very different. The body that is struck acquires, in the instant of impulse, a sensible quantity of motion, and fometimes a very rapid motion. This motion is neither

the rapidity of the motion depends, inter alia, on the previous velocity of the firiking body. For inflance, if a clay ball, moving with any velocity, strike another equal ball which is at reft, the struck ball moves with half the velocity of the other. And it is farther remarkable, that the striking body always loses as much motion as the flruck body gains This univerfal and remarkable fact feems to have given rife to a confufed or indiffinct notion of a fort of transference of motion from one body to another. The phraseology in general use on this subject expresses this in the most precise terms. The one ball is not faid to cause or produce motion in the other, but to communicate motion to it; and the whole phenomenon is called the communication of motion. We call this an indiffine notion; for furely Com no one will fay that he has any clear conception of it. Catio We can form the most distinct notion of the communia a got cation of heat, or of the cause of heat; of the communication cation of faltness, sweetness, and a thousand other things; but we cannot conceive how part of that identical motion which was formerly in A, is now infused into B, being given up by A. It is in our attempt to form this notion that we find that motion is not a thing, not a fubstance which can exist independently, and is susceptible of actual transference. It appears in this case to be a state, or condition, or mode of existence, of which bodies are fusceptible, which is producible, or (to speak without metaphor) causable, in bodies, and which is the effect and characteristic of certain natural qualities, properties, or powers. We are anxious to have our readers impressed with clear and precise notions on this subject, being confident that such, and only fuch, will carry them through fome intricate paths of mechanical and philosophical research.

The remarkable circumstance in this phenomenon is, Inhere that a rapid motion, which requires for the effecting it force in the action of a preffing power, continued for a fenfible, difting and frequently a long time, feems to be effected in an impulsion. This has tended much to fupport the notion of the actual transference of fomething formerly possessed exclusively by the striking body, inhering in it, but feparable, and now transfused, into the body stricken. And now room is found for the employment of metaphor, both in thought and language. The firiking body affects the body which it thus impels: It therefore possesses the power of impulsion, that is, of communicating motion. It possesses it only while it is in motion. This power, therefore, is the efficient dislinguishing cause of its motion, and its only office must be the continuation of this motion. It is therefore called the inherent force, the force inkerent in a moving body, vis insita corpori moto. This force is transfused into the body impelled; and therefore the transference is inftantaneous, and the impelled body continues its motion till it is changed by fome other action. All this is at first fight very plausible; but a ferupulous attention to those feelings which have given rife to this metaphorical conception, should have produced very different notions. I am confcious of exertion in order to begin motion on a flide; but if the ice be very fmooth, I am conscious of no exertion in order to flide along. My power is felt only while I am confcious of exerting it: Therefore I have no primitive accelerated nor retarded after the stroke, unless it be af- feeling or notion of power while I am sliding along. I

Gravity, at-Aractions.

9 Examples of impul-Lion.

am certain that no exertion of power is necessary here. evidence that there are two kinds of mechanical forceNo diffe-Nay, I find that I cannot think of my moving forward without effort otherwise than as a certain mode of my existence. Yet we imagine that the partifans of this opinion did really deduce it in some shape from their feelings. We must continue the exertion of walking in order to walk on; our power of walking must be contireally exerted, otherwise we shall stop. But this is a very imperfect, incomplete, and careless observation. Walking is much more than mere continuance in progressive motion. It is a continually repeated lifting our body up a fmall height, and allowing it to come down again. This renewed afcent requires repeated exertion.

We have other observations of importance yet to nsinite- make on this force of moving bodies, but this is not the most proper occasion. Meanwhile we must remark, that the inflantaneous production of rapid motion by impulse has induced the first mechanicians of Europe to maintain, that the power or force of impulse is unfusceptible of any comparison with a pressing power. They have afferted, that impulse is infinitely great when compared with preffure; not recollecting that they held them to be things totally disparate, that have no proportion more than weight and fweetness. But these gentlemen are perpeturly enticed away from their creed by the fimilarity of the ultimate refults of preffure and impulse. No person can find any difference between the motion of two balls moving equally fwift, in the same direction, one of which is descending by gravity and the other has derived its motion from a blow. This struggle of the mind to maintain its faith, and yet accommodate its doctrines to what we fee, has occafioned fome other curious forms of expression. Pressure is considered as an effort to produce motion When a ball lies on a table, its weight, which they call a power, continually and repeatedly endeavours (mark the meta-phorical word and thought) to move the ball downward. But these efforts are ineffectual. They fay that this ineffectual power is dead, and call it a vis MORTUA: but the force of impulsion is called a vis VIVA, a living force. But this is very whimfical and very inaccurate. If the impelling ball falls perpendicularly on the other lying on the table, it will produce no motion any more than gravity will; and if the table be annihilated, gravity becomes a vis viva.

We must now add, that in order to prove that imfinet pulse is infinitely greater than pressure, these mechaniciincon- ans turn our attention to many familiar facts which plead strongly in their favour. A carpenter will drive a nail into a board with a very moderate blow of his hammer. This will require a preffure which feems many hundred times greater than the impelling effort of the carpenter. A very moderate blow will shiver into pieces a diamond which would carry the weight of a mountain. Seeing this prodigious superiority in the impulse, how shall they account for the production of motion by means of pressure? for this motion of the hammer might have been acquired by its falling from a height; nay, it is actually acquired by means of the continued preffure of the carpenter's arm. They consider it as the aggregate of an infinity of succeeding pressures in every instant of its continuance; fo that the infignificant smallness of each effort is compensated by their inconceiveable

On the whole, we do not think that there is clear

effentially different in their nature. It is virtually gi-rence beven up by those who say that impulse is infinitely great-fion and er than pressure. Nor is there any considerable advan-impulsion, tage to be obtained by arranging the phenomenon under those two heads. We may perhaps find some method of explaining fatisfactorily the remarkable diffe. rence that is really observed in the two modes of producing motion; namely, the gradual production of motion by acknowledged preffure, and the instantaneous production of it by impulse. Indeed, we should not have taken up so much of our readers attention with this fubject, had it not been for fome inferences that have been made from these premises, which meet us in our very entry on the confideration of first principles, and that are of extensive influence on the whole science of mechanical philosophy, and, indeed, on the whole study of nature.

Mechanicians are greatly divided in their opinion Is impulabout the nature of the fole moving force in nature fion the fole Those whom we are now speaking of, seem to think cause of that all motion is produced by pressure: For when they consider impulse as equivalent to the aggregate of an infinity of repeated preffures, they undoubtedly fuppofe any pressure, however infignificant, as a moving force. But there is a party, both numerous and refpectable, who maintain that impulsion is the fole cause of motion. We fee bodies in motion, fay they, and wefee them impel others; and we fee that this production of motion is regulated by fuch laws, that there is but one absolute quantity of motion in the universe which remains unalterably the same. It must therefore be transfused in the acts of collision. We also see, with clear evidence, in some cases, that motion can produce preffure. Euler adduces fome very whimfical and complicated cases, in which an action, precisely similar to presfure, may be produced by motion. Thus, two balls connected by a thread, may be so struck that they shall move forward, and at the fame time wheel round. In this cafe the connecting thread will be stretched between them. Now, fay the philosophers, fince we see motion, and see that pressure may be produced by motion, it is preposterous to imagine that it is any thing elfe than a refult of certain motions; and it is the buliness of a philosopher to inquire and discover what motions produce the pressures that we observe.

They then proceed to account for those preffing powers, or folicitations to motion, which we observe in the acceleration of falling bodies, the attractions of magnetism and electricity, and many other phenomena of this kind, where bodies are put in motion by the vicinity of other bodies, or (in the popular language) by the action of other bodies at a diftance. To fay that a magnet can act on a piece of remote iron, is to fay that it can act where it is not; which is as abfurd as to fay, that it can act when it is not. Nihil movetur, fays Eu-

ler, nisi a contiguo et moto.

The bulk of thefe philosophers are not very anxious How does about the way in which these motions are produced, it produce nor do they fall upon fuch ingenious methods of pro-pressure? ducing pressure as the one already mentioned, which was adduced by Euler. The piece of iron, fay they, is put in motion when brought into the neighbourhoodof a magnet, because there is a stream of sluid issuing from one pole of the magnet, which circles round the

magnet,

magnet, and enters at the other pole: This stream impels the iron, and arranges it in certain determined pofitions, just as a stream of water would arrange the flote grass. In the same manner, there is a stream of fluid continually moving towards the centre of the earth, which impels all bodies in lines perpendicular to the furface; and fo on with regard to other like phenomena. These motions are thus reduced to very finiple cases by impulsion.

Incompa-

Others maintain that pref-

It is unnecessary to refute this doctrine at prefent; the rules of it is enough that it is contrary to all the dictates of philosophi. common sense. To suppose an agent that we do not see, and for whose existence we have not the smallest argument; with equal propriety we might suppose ministering spirits, or any thing that we please.

Other philosophers are so dissatisfied with this notion of the production of pressure, that they, on the other hand, affirm that preffure is the only moving force in nature; not according to the popular notion of preffole moving fure, by the mutual contact of folid bodies, but that kind of pressure which has been called solicitation; such as the power of gravity. They affirm, that there is no fuch thing as contact on inflantaneous communication of motion by real collision. They fay (and they prove it by very convincing facts (fee Optics, no 63-68. En. cycl.), that the particles of folid bodies exert very strong repulsions to a small distance; and therefore, when they are brought by motion sufficiently near to another body, they repel it, and are equally repelled by it. Thus is motion produced in the other body, and their own motion is diminished. And they then shew, by a scrupulous confideration of the state of the bodies while the one is advancing and the other retiring, in what manner the two bodies attain a common velocity, fo that the quantity of motion before collision remains unchanged, the one body gaining as much as the other loses. They also shew cases of such mutual action between bodies, where it is evident that they have never come into contact; and yet the refult has been precifely fimilar to those cases where the motion appeared to be changed in an inflant. Therefore they conclude, that there is no fuch thing as inflantaneous communication, or transfusion of motion, by contact in collision or impulse. The reason why previous motion of the impelling body is necessary, is not that it may have a vis infita corpori moto, a force inherent in it by its being in motion, but that it may continue to follow the impelled and retiring body, and exert on it a force inherent in itself, whether in motion or at relt. - According to these philosophers, therefore, all moving forces are of that kind which has been named folicitation; fuch as gravity. We shall know it afterwards by the more familiar and descriptive name of Accelerating or Retarding force.

The exertions of mechanical forces are differently fistance, Re- termed, according to the reference that we make to the refult. If, in boxing or wreftling, I ftrike, or endeavour to throw my antagonist, I am faid to ACT; but if I only party his blows, or prevent him from throwing me, I am faid to RESIST. This distinction is applied to the exertions of mechanical powers. When one body A changes the motion of another B, we may confider the change in the motion of B either as the indication and measure of A's power of producing motion, or as the indication and measure of A's resistance to the being brought to rest, or having its motion any how

changed. The distinction is not in the thing itself, but only in the reference that we are disposed, by other considerations, to make of its effect. They may be diffinguished in the following manner: If a change of motion follow when one of the powers ceases to be exerted, that power is conceived as having refifted. The whole language on this subject is metaphorical. Refistance, effort, endeavour, &c, are words which cannot be employed in mechanical discussions without figure, because they all express notions which relate to sentient beings; and the unguarded indulgence of this figurative language has fo much affected the imagination of philosophers, that many have almost animated all matter. Perhaps the word REACTION, introduced (we think) by Newton, is the best term for expressing that mutual force which is perceived in all the operations of nature that we have investigated with success. As the magnet attracts iron, and in fo doing is faid to all on it; fo the iron attracts the magnet, and may be faid to react on it.

With respect to the difficulty that has been objected We to the opinion of those who maintain that all the me-not chanical phenomena are produced by the agency of at-action tracting or repelling forces; namely, that this supposes distant the bodies to act on each other at a distance, however Tende fmall those distances may be, which is thought to be abfurd, we may observe, that we may ascribe the mutual approaches or recesses to tendencies to or from each other. What we call the attraction of the magnet may be confidered as a tendency of the iron to the magnet, somewhat similar to the gravitation of a stone toward the earth. We furely (at least the unlearned) can and do conceive the iron to be affected by the magnet, without thinking of any intermedium. The thing is not therefore inconceivable; which is all that we know about abfurdity: and we do not know any thing about the nature or effence of matter which renders this tendency to the magnet impossible. That we do not fee intuitively any reason why the iron should approach the magnet, must be granted; but this is not enough to intitle us to fay, that fuch a thing is impeffible or inconfistent with the nature of matter. It appears, therefore, to be very hafty and unwarrantable, to suppose the impulse of an invisible fluid, of which we know nothing, and of the existence of which we have no proof. Nay, if it be true that bodies do not come into contact, even when one ball hits another, and drives it before it, this invisible fluid will not solve the difficulty; because the fame difficulty occurs in the action of any particle of the fluid on the body. We are obliged to fay, that the production of motion without any observed contact, is a much more familiar phenomenon than the production of motion by impulsion. More motion has been produced in this way by the gravitation of a small stream of water, running ever fince the creation, than by all the impulses in the world twice told. We do not mean by this to fay, that the giving to this observed mutual relation between iron and a loadstone the name tendency makes it less absurd, than when we say that the loadstone attracts the iron; it only makes it more conceivable: It suggests a very familiar analogy; but both are equally figurative expressions; at least as the word tendency is used at present. In the language of ancient Rome, there was no metaphor when Virgil's hero faid, Tendimus in Latium. Tendere versus solem means, in plain

14 Action, Rewilliam.

plain Latin, to approach the fun. The fafe way of conceiving the whole is to fay, that the condition of the iron depends on the vicinity of the magnet.

raction, When the exertions of a mechanical power are obferved to be always directed toward a body, that body figurais faid to attract; but when the other body always moves off from it, it is faid to repel. These also are metaphorical expressions. I attract a boat when I pull it toward me by a rope; this is purely ATTRAC-TION: and it is pure, unfigurative REPULSION, when I push any body from me. The same words are applied to the mechanical phenomena, merely because they resemble the results of real attraction or repulfion. We must be much on our guard to avoid metaphor in our conceptions, and never allow those words to suggest to our mind any opinion about the manner in which the mechanical forces produce their effects. It is plain, that if the opinion of those who maintain the existence and action of the above mentioned invisible fluid be just, there is nothing like attraction or repulsion in the universe. We must always recur to the simple phenomenon, the motion to or from the attracting or repelling body; for this is all we see, and generally all that we know.

We conceive one man to have twice the strength of ces are resident another man, when we fee that he can withstand the reasur- united effort of two others. Thus animal force is conquan- ceived as a quantity, made up of, and measured by, its own parts. But we doubt exceedingly whether this be an accurate conception. We have not a distinct notion of one strain added to another; though we have of their being joined or combined. We want words to express the difference of these two notions in our own minds; but we imagine that others perceive the same difference. We conceive clearly the addition of two lines or of two minutes; we can conceive them apart, and perceive their boundaries, common to both, where one ends and the other begins. We cannot conceive thus of two forces combined; yet we cannot fay, that two equal forces are not double of one of them. We measure them by the effects which they are known to produce. Yet there are not wanting many cases where the action of two men, equally strong, does not produce a double motion.

In like manner, we conceive all mechanical forces as measurable by their effects; and thus they are made the subjects of mathematical discussion. We talk of the proportions of gravity, magnetism, electricity, &c.; nay, we talk of the proportion of gravity to magnetism :- Yet these, considered in themselves, are disparate, and do not admit of any proportion; but they produce effects, some of which are measurable, and whose assumed measures are susceptible of comparison, being quantities of the same kind. Thus, one of the effects of gravity is the acceleration of motion in a falling body: magnetifm will also accelerate the motion of a piece of iron; these two accelerations are comparable. But we cannot compare magnetism with heat; because we do not know any measurable effects of magnetism that are of the same kind with any effects of

3600th part of the gravitation at the sea shore, we mean that the fall of a stone in a second is 3600 times SUPPL. VOL. I. Part II.

But we also mean (and this expresses the proportion of the tendency of gravitation more purely), that if a stone, when hung on a spring steelyard, draw out the rod of the fleelyard to the mark 3600, the same stone, taken up to the distance of the moon, will draw it out no further than the mark 1. We also mean, that if the stone at the fea-shore draw out the rod to any mark, it will require 3600 fuch stones to draw it out to that mark, when the trial is made at the distance of the moon. It is not, therefore, in consequence of any immediate perception of the proportion of the gravitation at the moon to that at the furface of the earth that we make fuch an affertion; but these motions, which we consider as its effects in these fituations, being magnitudes of the fame kind, are susceptible of comparison, and have a proportion which can be ascertained by observation. It is these proportions that we contemplate; although we fpeak of the proportions of the unseen causes, the forces, or endeavours to descend. It will be of material fervice to the reader to peruse the judicious and acute differtation on quantity in the 45th volume of the Philosophical Transactions; or he may study the article QUANTITY in the Encyclopadia, where, we trust he will fee clearly how force, velocity, denfity, and many other magnitudes of very frequent occurrence in mechanical philosophy, may be made the subjects of mathematical discussion, by means of some of those proper quantities, measurable by their own parts, which are to be assumed as their measures. Pressures are measurable only by pressures. When we consider them as moving powers, we should be able to measure them by any moving powers, otherwise we cannot compare them; therefore it is not as pressures that we then measure them. This observation is momentous.

One circumstance must be carefully attended to. That those assumed measures may be accurate, they must be invariably connected with the magnitudes which they are employed to measure, and so connected, that the degrees of the one must change in the same manner with the degrees of the other. This is evident, and is granted by all. But we must also know this of the meature we employ; we must see this constant and precise relation. How can we know this? We do not perceive force as a separate existence, so as to see its proportions, and to see that these are the same with the proportions of the measures, in the same manner that Euclid fees the proportions of triangles and those of their bases, and that thefe proportions are the same, when the triangles are of equal altitudes. How do we difcover that to every magnitude which we call force is invariably attached a corresponding magnitude of acceleration or deflection? - Clearly. In fact, the very existence of the force is an inference that we make from the observed acceleration; and the degree of the force is, in like manner, an inference from the obferved magnitude of the acceleration. Our measures are therefore necessarily connected with the magnitudes which they measure, and their proportions are the same; because the one is always an inference from the other, both in species and in degree.

It is now evident, that these disquisitions are susceptible Dynamics When we say, that the gravitation of the moon is the tible of mathematical accuracy. Having selected our is a demonmeasures, and observed certain mathematical relations arrative of those measures, every inference that we can drawscience. greater than the fall of the moon in the same time, from the mathematical relations of the proportions of

3 S

19

those representations is true of the proportions of the motions; and therefore of the proportions of the forces. And thus dynamics becomes a demonstrative science,

one of the disciplina accurata.

But moving forces are confidered as differing also in kind; that is, in direction. We assign to the force the direction of the observed change of motion; which is not only the indication, but also the characteristic, of the changing force. We call it an accelerating, retarding, deflecting, force, according as we observe the motion to be accelerated, retarded, or deflected.

Thefe denominations shew as incontestably that we have no knowledge of the forces different from our knowledge of the effects. The denominations are all either descriptive of the effects, as when we call them accelerating, penetrating, protrufive, attractive, or repullive forces; or they are names of reference to the fuoftances in which the accelerating, protrufive, &c. forces, are supposed to be inherent, as when we call them

magnetism, electricity, corpuscular, &c.

When I struggle with another, and feel, that in order to prevent being thrown, I must exert force, I learn position to that my antagonist is exerting force. This notion is transferred to matter; and when a moving power which is known to operate, produces no motion, we conceive it to be opposed by another equal force; the existence, agency, and intenfity of which is detected and mea-fured by these means. The quiescent state of the body is confidered as a change on the state of things that would have been exhibited in confequence of the known action of one power, had this other power not acted; and this change is confidered as the indication, characteristic, and measure, of another power, detected in this way. Thus forces are recognifed not only by the changes of motion which they produce, but also by the changes of motion which they prevent. The cohesion of matter in a string is inferred not only by its giving motion to a ball which I pull toward me by its intervention, but also by its suspending that ball, and hindering it from falling. I know that gravity is acting on the ball, which, however, does not fall. The folidity of a board is equally inferred from its stopping the ball which strikes it, and from the motion of the ball which it drives before it. In this way we learn that the particles of tangible matter coliere by means of moving forces, and that they refift compression with force; and in making this inference, we find that this corpufcular soice exerted between the particles is mutual, opposite, and equal: for we must apply force equally to a or to b, in order to produce a separation or a compression. We learn their equality, by observing that no motion enfues while thefe mutual forces are known to act on the particles; that is, each is opposed by another force, which is neither inferior nor fuperior to it.

OF THE LAWS OF MOTION.

Such, then, being our notions of mechanical forces, the causes of the fensible changes of motion, there will refult certain consequences from them, which may be called axioms or laws of motion. Some of these may be intuitive, offering themselves to the mind as foon as the notions which they involve are presented to it. Others may be as necessary results from the relations of these notions, but may not readily offer themselves

without the mediation of axioms of the first class. We First shall select those which are intuitive, and may be taken of M for the first principles of all discussions in mechanical philosophy.

FIRST LAW OF MOTION.

Every body continues in a flate of rest, or of uniform rectilineal motion, unless affected by some mechanical force.

This is a proposition, on the truth of which the whole 22 science of mechanical philosophy ultimately depends. It is therefore to be established on the sirmest foundation; and a folicitude on this head is the more justifiable, because the opinions of philosophers have been, and still are, extremely different, both with respect to the truth of this law, and with respect to the foundation on which it is built. These opinions are, in general, very obscure and unfatisfactory; and, as is natural, they influence the discussions of those by whom they are held through the whole science. Although of contradictory opinions one only can be just, and it may appear fufficient that this one be established and uniformly applied; yet a short exposition, at least, of the rest is neceffary, that the greatest part of the writings of the philosophers may be intelligible, and that we may avail ourfelves of much valuable information contained in them, by being able to perceive the truth in the midst of their imperfect or erroneous conceptions of it.

It is not only the popular opinion that rest is the Does natural state of body, and that motion is something fo-tinue reign to it, but it has been feriously maintained by the tion greatest part of those who are esteemed philosophers. nued They readily grant, that matter will continue at reft, tion? unless some moving force act upon it. Nothing seems necessary for matter's remaining where it is, but its continuing to exist. But it is far otherwise, fay they, with respect to matter in motion. Here the body is continually changing its relations to other things; therefore the continual agency of a changing cause is necesfary (by the fundamental principle of all philosophical discussion), for there is here the continual production of an effect. They fay that this metaphyfical argument receives complete confirmation (if confirmation of an intuitive truth be necessary) from the most familiar observation. We see that all motions, however violent, terminate in rest, and that the continual exertion of some force is necessary for their continuance.

These philosophers therefore affert, that the conti-Whin nual action of the moving cause is effentially necessary notion for the continuance of the motion : but they differelem among themselves in their notions and opinions about minds this cause. Some maintain, that all the motions in the universe are produced and continued by the immediate agency of Deity; others affirm, that in every particle of matter there is inherent a fort of mind, the Duris and of Teptux" of Aristotle, which they call an ELE-MENTAL MIND, which is the cause of all its motions and changes. An overweaning reverence for Greek learning has had a great influence in reviving this doctrine of Aristotle. The Greek and Roman languages are affirmed to be more accurate expressions of human thought than the modern languages are. In those ancient languages, the verbs which express motion are employed both in the active and passive voice; whereas we have only the active verb to move, for expressing

20 Forces are

Law both the state of motion and the act of putting in modion tion. "The stone moves down the slope, and noves all the pebbles which lie in its way:" but in the ancient languages, the mere state of motion is always expressed by the passive or middle voice. The accurate conception of the speakers is therefore extelled. The state of motion is expressed as it ought to be, as the result of a continual action." Kircular, movetur, is equivalent to "it is noved." According to these philosophers, every thing which moves is mind, and every thing that is moved is body.

The argument is futile, and it is false; for the modern languages are, in general, equally accurate in this instance: "fe mouvoir," in French; "fich bewegen," in German; "dvigatfu," in Slavonic; are all passive or reflected. And the ancients faid, that " rain falls, water runs, finoke rifes," just as we do. The ingenious author of Ancient Metaphysics has taken much pains to give us, at length, the procedures of those elementary minds in producing the oftenfible phenomena of local motion; but it feems to be merely an abuse of language, and a very frivolous abuse. This elemental mind is known and characterifed only by the effect which we ascribe to its action; that is, by the motions or changes of motions. Uniform and unexcepted experience shews us that these are regulated by laws as precise as those of mathematical truth. We consider nothing as more fixed and determined than the common laws of mechanism. There is nothing here that indicates any thing like spontaneity, intention, purpose; none of those marks by which mind was first brought into view: but they are very like the effects which we produce by the exertions of our corporeal forces; and we have accordingly given the name force to the causes of motion. It is surely much more apposite than the name mind, and conveys with much more readiness and perspicuity the very notions that we wish to convey.

We now wish to know what reason we have to think that the continual action of some cause is necessary for continuing matter in motion, or for thinking that rest is its natural state. If we pretend to draw any argument from the nature of matter, that matter must be known, as far as is necessary for being the soundation of argument. Its very existence is known only from observation; all our knowledge of it must therefore be derived from the same source.

If we take this way to come at the origin of this opinion, we shall find that experience gives us no authority for faying that rest is the natural condition of matter. We cannot fay that we have ever feen a body at rest; this is evident to every person who allows the validity of the Newtonian philosophy, and the truth of the Copernican system of the sun and planets; all the parts of this system are in motion. Nay, it appears from many observations, that the fun, with his attending planets, is carried in a certain direction, with a velocity which is very great. We have no unquestionable authority for faying that any one of the stars is absolutely fixed; but we are certain that many of them are in motion. Rest is therefore so rare a condition of body, that we cannot fay, from any experience, that it is its natural state.

It is easy, however, to see, that it is from observation that this opinion has been derived; but the obser-

vation has been limited and careless. Our experiments First Law in this fublunary world do indeed always require conti-of Motion. nued action of some moving force to continue the motion; and if this be not employed, we see the motions stacken every minute, and terminate in rest after no long period. Our first notions of sublunary bodies are indicated by their operation in cases where we have some interest. Perpetually seeing our own exertions necessary, we are led to confider matter as fomething not only naturally quiefcent and inert, but fluggish, averse from motion, and prone to rest (we must be pardoned this metaphorical language, because we can find no other term). What is expressed by it, on this occasion, is precifely one of the erroneous or inadequate conceptions that are suggested to our thoughts by reason of the poverty of language. We animate matter in order to give it motion, and then we endow it with a fort of moral character in order to explain the appearance of those motions.

But more extended observation has made men gradually defert their first opinions, and at last allow that matter has no peculiar aptitude to rest. All the retardations that we observe have been discovered, one after another, to have a distinct reference to some external circumstances. The diminution of motion is always observed to be accompanied by the removal of obstacles, as when a ball moves through fand, or water, or air; or it is owing to opposite motions which are destroyed; or it is owing to roughness of the path, or to friction, &c. We find that the more we can keep those things out of the way, the less are the motions diminished. A pendulum will vibrate but a short while in water; much longer in air; and in the exhausted receiver, it will vibrate a whole day. We know that we cannot remove all obstacles; but we are led by such obfervations to conclude that, if they could be completely removed, our motions would continue for ever. And this conclusion is almost demonstrated by the motions of the heavenly bodies, to which we know of no obstacles, and which we really observe to retain their motions for many thousand years without the smallest senfible diminution.

Another set of philosophers maintain an opinion di-Inactivity rectly opposite to that of the inactivity of matter, and of matter affert, that it is effentially active, and continually chan-denied by ging its flate. Faint traces of this are to be found in Leibnitz. the writings of Plato, Aristotle, and their commentators. Mr Leibnitz is the perfon who has treated this question most systematically and fully. He supposes Monade, every particle of matter to have a principle of indivi-what. duality, which he therefore calls a Monap. This monad has a fort of perception of its situation in the universe, and of its relation to every other part of this universe. Lastly, he says that the monad acts on the material particle, much in the fame way that the foul of man acts on his body. It modifies the motion of the material atom (in conformity, however, to unalterable laws), producing all those modifications of motion that we observe. Matter therefore, or, at least, particles of matter, are continually active, and continually changing their fituation.

It is quite unnecessary to enter on a formal consistant This opition of Mr Leibnitz's system of monads, which differs nion illvery little from the system of elemental minds, and is founded. equally whimsical and frivolous; because it only makes

3 S 2

the

26

Law the unlearned reader stare, without giving him any inof Motion formation. Should it even be granted, it would not, any more than the action of animals, invalidate the general proposition which we are endeavouring to establish as the fundamental law of motion. Those powers of the monads, or of the elemental minds, are the causes of all the changes of motion; but the mere material particle is subject to the law, and requires the exertion of the monad in order to exhibit a change of

28 Some phizing cause.

A third feet of philosophers, at the head of which we may place Sir Isaac Newton, maintain the doctrine law of mo. enounced in the proposition. But they differ much in tion from respect of the foundation on which it is built.

Some affert that its truth flows from the nature of the thing. If a body he at rest, and you affert that it will not remain at rest, it must move in some one direction. If it be in motion in any direction, and with any velocity, and do not continue its equable, rectilineal, motion, it must either be accelerated or retarded; it must turn either to one side, or to some other side. The event, whatever it be, is individual and determinate; but no cause which can determine it is supposed: there. fore the determination cannot take place, and no change will happen in the condition of the body with respect to motion. It will continue at rest, or persevere in its rectilineal and equable motion.

But considerable objections may be made to this argument, of fufficient reason, as it is called. In the immensity and perfect uniformity of space and time, there is no determining cause why the visible universe should exist in the place in which we see it rather than in another, or at this time rather than at another. Nay, the argument feems to beg the question. A cause of determination is required as effentially necessary-a determination may be without a cause, as well as a motion

without a cause.

Other philosophers, who maintain this doctrine, confider it merely as an experimental truth; and proofs of its univerfality are innumerable.

When a stone is thrown from the hand, we press it forward while in the hand, and let it go when the hand has acquired the greatest rapidity of motion that we can give it. The stone continues in that state of motion which it acquired gradually along with the hand. We can throw a stone much farther by means of a sling; because, by a very moderate motion of the hand, we can whirl the stone round till it acquire a very great velocity, and then we let go one of the strings, and the stone escapes, by continuing its rapid motion. We see it still more distinctly in shooting an arrow from a bow. The string presses hard on the notch of the arrow, and it yields to this pressure and goes forward. The string alone would go faster forward. It therefore continues to press the arrow forward, and accelerates its motion. This goes on till the bow is as much unbent as the string will allow. But the string is now a straight line. It came into this position with an accelerated motion, and it therefore goes a little beyond this position, but with a retarded motion, being checked by the bow. But there is nothing to check the arrow; therefore the arrow quits the string, and slies away.

These are simple cases of perseverance in a state of motion, where the procedure of nature is fo eafily traced that we perceive it almost intuitively. It is no less clear in other phenomena which are more complicated; Fin but it requires a little reflection to trace the process. of We have often seen an equestrian showman ride a horse at a gallop, standing on the saddle, and stepping from it to the back of another horse that gallops alongfide at the fame rate; and he does this feemingly with as much eafe as if the horses were standing still. The man has the same velocity with the horse that gallops under him, and keeps this velocity while he steps to the back of the other. If that other were standing still. the man would fly over his head. And if a man should step from the back of a horse that is standing still to the back of another that gallops past him, he would be left behind. In the same manner, a slack wire dancer tosses oranges from hand to hand while the wire is in full fwing. The orange, fwinging along with the hand, retains the velocity; and when in the air follows the hand, and falls into it when it is in the opposite extremity of its swing. A ball, dropped from the mast head of a ship that is sailing briskly forward, falls at the foot of the mast. It retains the motion which it had while in the hand of the person who dropped it, and follows the mast during the whole of its fall.

We also have familiar instances of the perseverance of a body in a state of rest. When a vessel filled with water is drawn suddenly along the floor, the water dashes over the posterior side of the vessel. It is left behind. In the same manner, when a coach or boat is dragged forward, the persons in it find themselves strike against the hinder part of the carriage or boat. Properly speaking, it is the carriage that strikes on them. In like manner, if we lay a card on the tip of the finger, and a piece of money on the card, we may nick away the card, by hitting it neatly on its edge; but the piece of money will be left behind, lying on the tip of the finger. A ball will go through a wall and fly onward; but the wall is left behind. Buildings are thrown down by earthquakes; fometimes by being toffed from their foundations, but more generally by the

wife from under them, &c.

But common experience feems infufficient for esta-Co: 100 blishing this fundamental proposition of mechanical phi-exp losophy. We must, on the faith of the Copernican sy. influie stem, grant that we never faw a body at rest, or in uniform rectilineal motion; yet this feems absolutely neceffary before we can fay that we have established this

ground on which they stand being hastily drawn side-

proposition experimentally.

What we imagine, in our experiments, to be putting a body, formerly at rest, into motion, is, in fact, only changing a most rapid motion, not less, and probably much greater, than 90,000 feet per fecond. Suppose a cannon pointed east, and the bullet discharged at noon day with 60 times greater velocity than we have ever been able to give it. It would appear to fet out with this unmeasurable velocity to the eastward; to be gradually retarded by the refistance of the air, and at last brought to rest by hitting the ground. But, by reason of the earth's motion round the sun, the fact is quite the reverse. Immediately before the discharge, the ball was moving to the westward with the velocity of 90,000 feet per fecond nearly. By the explosion of the powder, and its pressure on the ball, some of this motion is destroyed, and at the muzzle of the gun, the ball is moving flower, and the cannon is hurried away from it

Others deduce it from experience.

A Law to the westward. The air, which is also moving to the Morion westward 90,000 feet in a second, gradually communicates motion to the ball, in the fame manner as a hurricane would do. At last (the ball dropping all the while) some part of the ground hits the ball, and car-

ries it along with it.

Other observations must therefore be resorted to, in order to obtain an experimental proof of this proposition. And fuch are to be found. Although we cannot measure the absolute motions of bodies, we can observe and measure accurately their relative motions, which are the differences of their absolute motions. Now, if we can shew experimentally, that bodies shew equal tendencies to refift the augmentation and the diminution of their relative motions, they, ipso facto, shew equal tendencies to refift the augmentation or diminution of their absolute motions. Therefore let two bodies, A and B, be put into fuch a fituation, that they cannot (by reafon of their impenetrability, or the actions of their mutual powers) persevere in their relative motions. The change produced on A is the effect and the measure of B's tendency to perfevere in its former state; and therefore the proportion of these changes will shew the proportion of their tendencies to maintain their former flates. Therefore let the following experiment be made

Let A, apparently moving westward three feet per onth pro- fecond, hit the equal body B apparently at rest. Suppose, if, That A impels B forward, without any diminution of its own velocity. This refult would shew that B manifests no tendency to maintain its motion unchanged, but that A retains its motion undiminished.

2dly, Suppose that A stops, and that B remains at rest. This would shew that A does not resist a diminution of motion, but that B retains its motion unaug-

3dly, Suppose that both move weltward with the velocity of one foot per fecond. The change on A is a diminution of velocity, amounting to two feet per fecond. This is the effect and the measure of B's tendency to maintain its velocity unaugmented. The change on B is an augmentation of one foot per second made on its velocity; and this is the measure of A's tendeney to maintain its velocity undiminished. This tendency is but half of the former; and this result would shew, that the resistance to a diminution of velocity is but half of the refistance to augmentation. It is perliaps but one quarter; for the change on B has produced a double change on A.

athly, Suppose that both move westward at the rate of 1' feet per second. It is evident that their tendencies to maintain their states unchanged are now equal.

5thly, Suppose A = 2 B, and that both move, after the collision, two feet per fecond, B has received an addition of two feet per fecond to its former velocity. This is the effect and the measure of A's whole tendency to retain its motion undiminished. Half of this change on B measures the persevering tendency of the half of A; but A, which formerly moved with the apparent or relative velocity three, now moves (by the supposition) with the velocity two, having lost a velocity of one foot per fecond. Each half of A therefore has lost this velocity, and the whole loss of motion is two. Now this is the measure of B's tendency to maintain its former flate unaugmented; and this is the

fame with the measure of A's tendency to maintain its First Law own former state undiminished. The conclusion from of Motion. fuch a refult would therefore be, that bodies have equal tendencies to maintain their former states of motion without augmentation and without diminution.

What is supposed in the 4th and 5th cases is really the result of all the experiments which have been tried; and this law regulates all the changes of motion which are produced by the mutual actions of bodies in impulfions. This affertion is true without exception or qualification. Therefore it appears that bodies have no preferable tendency to rest, and that no fact can be adduced which should make us suppose that a motion once begun should suffer any diminution without the action of a changing cause.

But we must now observe, that this way of establish- But expeing the first law of motion is very imperfect, and alto-rience is gether unfit for rendering it the fundamental principle per soundaof a whole and extensive science. It is subject to all tion of an the inaccuracy that is to be found in our best experi-axiom, ments; and it cannot be applied to cases where scrupulous accuracy is wanted, and where no experiment

can be made.

Let us therefore examine the proposition by means of the general principles adopted in the article Philo-SOPHY, Encycl. which contain the foundation of all our knowledge of active nature. These principles will, we imagine, give a decision of this question that is speedy and accurate; shewing the proposition to be an axiom or intuitive consequence of the relations of those ideas which we have of motion, and of the causes of its production and changes.

It has been fully demonstrated that the powers or Logical. forces, of which we speak so much, are never the imme-proof-diate objects of our perception. Their very existence, their kind, and their degree, are inflinctive inferences from the motions which we observe and class. It evidently follows from this experimental and univerfal trutin, 1st, That where no change of motion is observed, no fuch inference is made; that is, no power is supposed to act. But whenever any change of motion is observed, the inference is made; that is, a power or

force is supposed to have acted.

In the same form of logical conclusion, we must say that, 2dly, When no change of motion is supposed or thought of, no force is fupposed; and that whenever we suppose a change of motion, we, in fact, though not in terms, suppose a changing force. And, on the other hand, whenever we suppose the action of a changing force, we suppose the change of motion; for the action of this force, and the change of motion, is one and the same thing. We cannot think of the action without thinking of the indication of that action; that is, the change of motion .- In the fame manner, when we do not think of a changing force, or suppose that there is no action of a changing force, we, in fact, though not in terms, suppose that there is no indication of this changing force; that is, that there is no change.

Whenever, therefore, we suppose that no mechanical't is a law force is acting on a body, we, in fact, suppose that the of human body continues in its former condition with respect to thought, motion. If we suppose that nothing accelerates, or retards, or deflects the motion, we suppose that it is not accelerated, nor retarded, nor deflected. Hence follows the proposition in express terms-We suppose that

First Law the body continues in its former state of rest or motion, unof Motion. less we suppose that it is changed by some mechanical

Thus it appears, that this proposition is not a matter of experience or contingency, depending on the properties which it has pleased the Author of Nature to bestow on body: it is, to us, a necessary truth. The proposition does not so inuch express any thing with regard to body, as it does the operations of our mind when contemplating body. It may perhaps be effential to body to move in some particular direction. It may be effential to body to stop as soon as the moving cause has ceased to act; or it may be effential to body to diminish its motion gradually, and finally come to rest.

tion. These circumstances in the nature of body, which render those modifications of motion essentially necessary, are the causes of those modifications; and, in our study of nature, they will be considered by us as changing forces, and will be known and called by that name. And if we should ever see a particle of matter in such a fituation that it is assected by those essential

But this will not invalidate the truth of this proposi-

properties alone, we shall, from observation of its motion, discover what those essential properties are.

And almost This law turns out at last to be little more than a an identical tautological proposition: But mechanical philosophy, proposition. tautological proposition. Due included as we have defined it, requires no other sense of it; for, even if we should suppose that body, of its own nature, is capable of changing its state, this change must be performed according to some law which characterifes the nature of body; and the knowledge of the law can be had in no other way than by observing the deviations from uniform rectilineal motion. It is therefore indifferent whether those changes are derived from the nature of the thing, or from external causes: for in order to confider the various motions of bodies, we must first consider this nature of matter as a mechanical affection of matter, operating in every instance; and thus we are brought back to the law enounced in this proposition. This becomes more certain when we reflect that the external causes (such as gravity or magnetism), which are acknowledged to operate changes of motion, are equally unknown to us with this effential original property of matter, and are, like it, nothing but inferences from the phenomena.

position, as we have enounced it, many (and they too of the first eminence), reject it in sact, by combining it with other opinions which are inconsistent with it, nay, which contradict it in express terms. We may even include Sir Isaac Newton in the number of those who have at least introduced modes of expression which mislead the minds of incautious persons, and suggest inadequate notions, incompatible with the pure doctrine of

the proposition. Although, in words, they disclaim the doctrine that rest is the natural state of body, and that force is necessary for the continuation of its motion, yet in words they (and most of them in thought) likewise abet that doctrine: for they say, that there resides in a

moving body a power or farce, by which it perseveres in Fira its motion. They call it the VIS INSITA, the INHE- of M RENT FORCE OF A MOVING BODY. This is furely giving up the question: for if the motion is supposed to be continued in consequence of a force, that force is supposed to be exerted; and it is supposed, that if it were not exerted, the motion would cease; and therefore the proposition must be false. Indeed it is sometimes expressed so as seemingly to ward off this objection. It is faid, that the body continues in uniform rectilineal motion, unless affected by some external cause. But this way of speaking obliges us, at first fetting out in natural philosophy, to affert that gravity, magnetism, electricity, and a thousand other mechanical powers, are external to the matter which they put in motion. This is quite improper: It is the business of philosophy to discover whether they be external or not; and if we affert that they are, we have no principles of argumentation with those who deny it. It is this one thing that has filled the study of nature with all the jargon of æthers and other invihible intangible fluids, which has

difgraced philosophy, and greatly retarded its progress. We must observe, that the terms vis insita, inherent vis in force, are very improper. There is no dispute among inhere philosophers in calling every thing a force that pro-force, duces a change of motion, and in inferring the action impro of fuch a force whenever we observe a change of mo-their u tion. It is furely incongruous to give the fame name accept to what has not this quality of producing a change, or tion. to infer (or rather to suppose) the energy of a force when no change of motion is observed. This is one among many instances of the danger of mistake when we indulge in analogical discussions. All our language, at least, on this subject is analogous. I feel, that in order to oppose animal force, I must exert force. But I must exert force in order to oppose a body in motion: Therefore I imagine that the moving body possesses force. A bent spring will drive a body forward by unbending: Therefore I fay that the spring exerts force. A moving body impels the body which it hits: Therefore I fay, that the impelling body possesses and exerts force. I imagine farther, that it possesses force only by being in motion, or because it is in motion; because I do not find that a quiescent body will put another into motion by touching it. But we shall soon find this to be false in many, if not in all cases, and that the communication of motion depends on the mere vicinity, and not on the motion, of the impelling body; yet we ascribe the exertion of the vis insita to the circumstance of the continued motion. We therefore conceive the force as arifing from, or as confifting in, the impelling body's being in motion; and, with a very obscure and indiftinct conception of the whole matter, we call it the force by which the body preserves itself in motion. Thus, taking it for granted that a force refides in the body, and being obliged to give it some office, this is the only one that we can think of.

But philosophers imagine that they perceive the necessity of the exertion of a force in order to the continuation of a motion. Motion (say they) is a continued action; the body is every instant in a new situation; there is the continual production of an effect, therefore the continual action of a cause.

But this is a very inaccurate way of thinking. We have a distinct conception of motion; and we conceive

that

Law, that there is such a thing as a moving cause, which we Istion diffinguish from all other causes by the name force. It produces motion. If it does this, it produces the character of motion, which is a continual change of place. Motion is not action, but the effect of an action; and this action is as complete in the instant immediately effect forceeding the beginning of the motion as it is a minute after. The subsequent change of place is the continuation of an effect already produced. The immediate effect of the moving force is a DETERMINATION, by which, if not hindered, the body would go on for ever from place to place. It is in this determination only that the state or condition of the body can differ from a state of rest; for in any instant, the body does not describe any space, but has a determination, by which it will describe a certain space uniformly in a certain time. Motion is a condition, a state, or mode, of existence, and no more requires the continued agency of the moving cause than yellowness or roundness does. It requires fome chemical agency to change the yellowness to greenness; and it requires a mechanical cause or a force to change this motion into rest. When we fee a moving body stop short in an instant, or be gradually, but quickly, brought to rest, we never fail to speculate about a cause of this cessation or retardation. The case is no way different in itself although the retardation should be extremely slow. We should always attribute it to a cause. It requires a cause to put a body out of motion as much as to put it into motion. This canfe, if not external, must be found in the body itself; and it must have a self-determining power, and may as well be able to put itself into motion as out of it.

If this reasoning be not admitted, we do not see how any effect can be produced by any cause. Every effect supposes something done; and any thing done implies that the thing done may remain till it be undone by some other cause. Without this, it would have no existence. If a moving cause did not produce continued motion by its instantaneous action, it could not produce it by any continuance of that action; because in no instant of that action does it produce continued motion.

We must therefore give up the opinion, that there, resides in a moving body a force by which it is kept in motion; and we must find some other way of explaining that remarkable difference between a moving body and a body at rest, by which the first causes other bodies to move by hitting them, while the other does not do this by merely touching them. We shall see, with the clearest evidence, that motion is necessary in the impelling body, in order that it may permit the forces in herent in one or both bodies to continue this pressure long enough for producing a sensible or considerable motion. But these moving forces are inherent in bodies, whether they are in motion or at rest.

The foregoing observations show us the impropriety of the phrase communication of motion. By thus reflecting on the notions that are involved in the general contrast, ception of one body being made to move by the impulse of another, we perceive, that there is nothing individual transferred from the one body to the other. The determination to motion, indeed, existed only in the impelling body before collision; whereas, afterwards, both bodies are so conditioned or determined. But we

can form no notion of the thing transferred. With the First Law fame metaphysical impropriety, we speak of the com- of Motion munication of joy, of sever.

Kepler introduced a term INERTIA, VIS INERTIE, So is eis into mechanical philosophy; and it is now in constant inertia. use. But writers are very careless and vague in the notions which they affix to these terms. Kepler and Newton feen generally to employ it for expressing the fact, the perseverance of the body in its present state of motion or rest: but they also frequently express by it fornething like an indifference to motion or rest, manifested by its requiring the same quantity of force to make an augmentation of its motion as to make an equal diminution of it. The popular notion is like that which we have of actual relitance; and it always implies the notion of force exerted by the refifting body. We suppose this to be the exertion of the vis insita, or the inherent force of a body in 1. otion. But we have the same notion of relitance from a body at rest which we set in motion. Now furely it is in direct contradiction to the common use of the word force, when we suppose refishance from a body at rest; yet vis inertiae is a very common expression. Nor is it more absurd (and it is very abfurd) to fay, that a body maintains its state of rest by the exertion of a vis inertia, than to fay, that it maintains its flate of motion by the exertion of an inherent force. We should avoid all such metaphorical expressions as resistance, indifference, sluggishness, or proneness to rest (which some express by inertia), because they seldom fail to make us indulge in metaphorical notions, and thus lead us to misconceive the modus operandi, or procedure of nature.

There is no refissance whatever observed in these phenomena; for the force employed always produces its complete effect. When I throw down a man, and find that I have employed no more force than was fufficient to throw down a fimilar and equal mass of dead matter, I know by this that he has not refifted; but I conclude that he has refifted, if I have been obliged to employ much more force. I here is therefore no refiftance, properly fo called, when the exerted force is obferved to produce its full effect. To fay that there is refiftance, is therefore a real misconception of the way in which mechanical forces have operated in the collifion of bodies. There is no more relistance in these cases than in any other natural charges of condition. We are guilty, however, of the fame impropriety of language in other cuses, where the cause of it is more evident. We say that colours in grain refift the action. of foap and of the fun, but that Proffian blue does not. We all perceive, that in this expression the word refistance is entirely figurative: and we should fay that Pruffian blue refifts foap, if we are right in faying that a body refifts any force employed to change its state of motion; for foap must be employed to discharge or change the colour; and it does change it. Force must be employed to change a motion; and it does change it. The impropriety, both of thought and language, is plains in the one case, and it is no less real in the other. Both of the terms, inherent force and inertia, may be nifed with fafety for abbreviating language, if we be careful to employ them only for expressing, either the simple fact of persevering in the former state, or the necessity of employing a certain determinate force, in order to change that

From

berondLaw

force.

From the whole of this discussion, we learn, that the of Motion deviations from uniform motions are the indications of the existence and agency of mechanical forces, and that Deviations they are the only indications. The indication is very from uni- fimple, mere change of place; it can therefore indicate form recti- nothing but what is very fimple, the fomething comhneal motion are the petent to the production of the very motion that we only indica observe. And when two changes of motion are precifely fimilar, they indicate the fame thing. Suppose a mariner's compass on the table, and that by a small tap with my finger I cause the needle to turn off from its quiefcent position 10 degrees. I can do the same thing by bringing a magnet near it; or by bringing an electrified shody near it; or by the unbending of a fine fpring pressing it aside; or by a pust of wind; or by several other methods. In all these cases, the indication is the fame; therefore the thing indicated is the fame, namely, a certain intensity and direction of a moving power. How it operates, or in what manner it exists and exerts itself in these instances, outwardly so different, is not under confideration at present. Impulsiveness, intensity, and direction, are all the circumstances of resemblance by which the affections of matter are to be characterifed; and it is to the difcovery and determination of thefe alone that our attention is now to be directed. We are directed in this refearch by the

SECOND LAW OF MOTION.

Every change of motion is proportional to the force impressed, and is made in the direction of that force.

This law also may almost be considered as an identical proposition; for it is equivalent to saying, that the changing force is to be measured by the change which it produces, and that the direction of this force is the direction of the change. Of this there can be no doubt, when we consider the force in no other fense than that of the cause of motion, paying no attention to the form or manner of its exertion. Thus, when a pellet of tow is shot from a pop gun by the expansion of the air compressed by the rammer, or where it is shot from a toy pistol by the unbending of the coiled wire, or when it is nicked away by the thumb like a marble—if, in all thefe cases, it moves off in the same direction, and with the fame velocity, we cannot confider or think of the force, or at least of its exertion, as any how different. Nay, when it is driven forward by the inflantaneous percussion of a fmart stroke, although the manner of producing this effect (if possible) is effentially different from what is conceived in the other cases, we must still think that the propelling force, confidered as a propelling force, is one and the same. In short, this law of motion, as thus expressed by Sir Haac Newton, is equivalent to faying, "That we take the changes of motion as the measures of the changing forces, and the direction of the change for the indication of the direction of the forces:" For no reflecting person can pretend to fay, that it is a deduction from the acknowledged principle, that effects are proportional to their causes. We do not affirm this law, from having observed the proportion of the forces and the proportion of the changes, and that these proportions are the same; and from having observed that this has obtained through the whole extent of our fludy of nature. 'This would indeed establish it as a physical law, an universal fact: and it is, in fact, so established. But this does not esta-

blish it as a law of motion, according to our definition Second of that term; as a law of human thought, the refult of of M the relations of our ideas, as an intuitive truth. The injudicious attempts of philosophers to prove it as a matter of observation, have occasioned the only dispute that has arifen in mechanical philosophy. It is well -known, that a bullet, moving with double velocity, penetrates four times as far. Many other fimilar facts corroborate this: and the philosophers observe, that four times the force has been expended to generate this double velocity in the bullet; it requires four times as much powder. In all the examples of this kind, it would feem that the ratio of the forces employed has been very accurately afcertained; yet this is the invariable refult. Philosophers, therefore, have concluded, that moving forces are not proportional to the velocities which they produce, but to the squares of those velocities. It is a strong confirmation, to fee that the bodies in motion feem to possess forces in this very proportion, and produce effects in this proportion; penetrating four times as deep when the velocity is only twice as great,

But if this be a just estimation, we cannot reconcile it to the concession of the same philosophers, who grant that the velocity is proportional to the force impressed, in the cases where we have no previous observation of the ratio of the forces, and of its equality to the ratio of the velocities. This is the case with gravity, which these philosophers always measure by its accelerating power, or the velocity which it generates in a given time. And this cannot be refused by them; for cases occur, where the force can be meafured, in the most natural manner, by the actual preffure which it exerts. Gravity is thus measured by the pressure which a stone exerts on its supports. A weight which at Quito will pull out the rod of a fpring fleelyard to the mark 312, will pull it to 313 at Spitzbergen. And it is a fact, that a body will fall 313 inches at Spitzbergen in the fame time that it falls 312 at Quito. Gravitation is the cause both of the pressure and the fall; and it is a matter of unexcepted observation, that they have always the fame ratio. The philosophers who have so strenuously maintained the other measure of forces, are among the most eminent of those who have examined the motions produced by gravity, magnetism, electricity, &c.; and they never think of meafuring those forces any other way than by the velocity. It is in this way that the whole of the celestial phenomena are explained in perfect uniformity with observation, and that the Newtonian philosophy is considered as a demonstrative

There must, therefore, be some defect in the principle on which the other measurement of forces is built, or in the method of applying it. Preffure is undoubtedly the immediate and natural measure of force; yet we know that four springs, or a bow four times as strong, give only a double velocity to an arrow.

The truth of our law rests on this only, that we assume the changes of motion as the measure of the changing forces; or, at least, as the measures of their exertions in producing motion. In fact, they are the measures only of a certain circumstance, in which the actions of very different natural powers may refemble each other; namely, the competency to produce motion. They do not, perhaps, measure their competency to produce heat, or

and aweven to bend fprings. We can furely confider this a-Motion part from all other circumstances; and it is worthy of feparate consideration. Let us see what can be, and what ought to be, deduced from this way of treating

inge of The motion of a body may certainly remain unchanhano torceira no circum de velocity remain the fame, we perceive no circumstance in which its condition, with respect to motion, differs. Its change of place or fituation can make no difference; for this is implied in the very circumstance of the bodies being in motion.

But if either the velocity or direction change, then furely is its mechanical condition no longer the fame; a force has acted on it, either intrinsic or from without, either accelerating, or retarding, or deflecting it. Supposing the direction to remain the same, its difference of condition can confift in nothing but its difference of velocity. This is the only circumstance in which its condition can differ, as it passes through two different points of its rectilineal path. It is this determination by which the body will deferibe a certain determinate space uniformly ima given time, which defines its condition as a moving body: the changes of this determination are the measures of their own causes; - and to those causes we have given the name force. Those causes may reside in other bodies, which may have other properties, characterifed and measured by other effects. Pressure may be one of those properties, and may have its own measures; these may, or may not, have the fame proportion with that property which is the cause of a change of velocity: and therefore changes of velocity may not be a measure of pressure. This is a question of fact, and requires observation and experience; but, in the mean time, velocity, and the change of velocity, is the measure of moving force and of changing force. When therefore the change of velocity is the same, whatever the previous velocity may be, the changing force must be considered as the same: therefore, finally, if the previous velocity is nothing, and confequently the change on that body is the very velocity or motion that it acquires, we must say, that the force which produces a certain change in the velocity of a moving body, is the same with the force which would impart to a body at rest a velocity equal to this change or differenee of velocity produced on the body already in mo-

This manner of estimating force is in perfect conformity to our most familiar notions on these subjects. We conceive the weight or downward pressure of a body as the cause of its motion downwards; and we conceive it as belonging to the body at all times, and in all places, whether falling, or rifing upwards, or describing a parabola, or lying on a table; and, accordingly, we observe, that in every state of motion it receives equal changes of velocity in the same, or an equal time, and all in the direction of its pressure.

All that we have now faid of a change of velocity might be repeated of a change of direction. It is furely possible that the same change of direction may be made on any two motions. Let one of the motions be considered as growing continually slower, and terminating in rest. In every instant of this motion it is possible to make one and the same change on it. The same change may therefore be made at the very instant that the mo-

SUPPL. VOL. I. Part II.

motion which the body acquires from the changing Secondl.aw force. Therefore, in this case also, we must say, that a of Motion. change of motion is itself a motion, and that it is the motion which the force would produce in a body that was previously at rest.

The refult of these observations is evidently this, How afterthat we must ascertain, in every instance, what is the tained and change of motion, and mark it by characters that are measured. conspicuous and dislinguishing; and this mark and meafure of change must be a motion: Then we must fay, that the changing force is that which would produce this motion in a body previously at rest. We must see how this is manifest, as a motion, in the difference between the former motion and the new motion; and, on the other hand, we must see how the motion produceable in a quiescent body may be so combined with a motion already existing, as to exhibit a new motion, in which the agency of the changing force may appear.

Suppose a ship at anchor in a stream; while one man walks forward on the quarter deck at the rate of two miles per hour, another walks from stem to stern at the fame rate, a third walks athwart ship, and a fourth stands still. Let the ship be supposed to cut or part her cable, and float down the stream at the rate of three miles per hour. We cannot conceive any difference in the change made on each man's motion in absolute space; but their motions are now exceedingly different from what they were: the first man, whom we may suppose to have been walking westward, is now moving eastward one mile per hour; the second is moving eastward four miles per hour; and the third is moving in an oblique direction, about three points north or fouth of due eaft. All have fuffered the same change of condition with the man who had been flanding still. He has now got a motion eastward three miles per hour. In this instance, we see very well the circumstance of sameness that obtains in the change of these four conditions. It is the motion of the ship, which is blended with the other motions. But this circumstance is equally present whenever the same previous motions are changed into the same new motions. We must learn to expifcate this; which we shall do, by considering the manner in which the motion of the ship is blended with each of the mens motions.

This kind of combination has been called the Composisition of motion; because, in every point of the motion of motion really purfued, the two motions are to be found.

The fundamental theorem on this subject is this: -I'wo uniform motions in the fides of a parallelogram compose an uniform motion in the diagonal.

Suppose that a point A (fig. 1.) describes AB uni-Plate XXI. formly in some given time, while the line AB is carried uniformly along AC in the same time, keeping always parallel to its first position AB. The point A, by the combination of these motions, will describe AD. the diagonal of the parallelogram ABDC, uniformly in the fame time.

For it is plain, that the velocities in AB and AC are proportional to AB and AC, because they are uniformly described in the same time. When the point. has got to E, the middle of AB, the line AB has got into the situation GH, half way between AB and CD. and the point E is in the place e, the middle of GH. Draw Ee L parallel to AC. It is plain, that the pation is at an end. In this case, the change is the very rallelograms ABDC and AE &G are similar; because

Secon Law AE and AG are the halves of AB and AC, and the of Motion angle at A is common to both. Therefore, by a proposition in the elements, they are about the same diagonal, and the point e is in the diagonal of AD. In like manner, it may be shewn, that when A has described AF, 3ths of AB, the line AB will be in the fituation IK, so that AI is 3ths of AC, and the point f, in which A is now found, is in the diagonal AD. It will be the same in whatever point of AB the describing point A be supposed to be found. The line AB will be on a similar point of AC, and the describing point will be in the diagonal AD.

Moreover, the motion in AD is uniform: for Ae is described in the time of describing AE; that is, in half the time of describing AB, or in half the time of describing AD. In like manner, Af is described in 3ths of the time of describing AD, &c. &c.

Laftly, the velocity in the diagonal AD is to the velocity in either of the fides as AD is to that fide. This is evident, because they are uniformly described in the

This is justly called a composition of the motions AB and AC, as will appear by confidering it in the following manner: Let the lines AB AC be conceived as two material lines like wires. Let AB move uniformly from the situation AB into the situation CD, while AC moves uniformly into the fituation BD. It is plain, that their intersection will always be found on AD. The point e, for example, is a point common to both lines. Considered as a point of EL, it is then moving in the direction eH or AB; and, confidered as a point of GH, it is moving in the direction e L. Both of these motions are therefore blended in the motion of the intersection along AD. We can conceive a small ring at e, embracing loosely both of the wires. This material ring will move in the diagonal, and will really partake of both motions.

Thus we see how the motion of the ship is actually blended with the motions of the three men; and the circumstance of sameness which is to be found in the four changes of motion is this motion of the ship, or of the man who was standing still. By composition with each of the three former motions, it produces each of the three new motions. Now, when each of two primitive motions is the same, and each of the new motions is the same, the change is surely the same. If one of the changes has been brought about by the actual composition of motions, we know precisely what that change is; and this informs us what the other is, in whatever way it was produced. Hence we infer,

When a motion is any how changed, the change is that motion which, when compounded with the former motion, will produce the new motion. Now, because we assume the change as the measure and characteristic of the changing force, we must do so in the present instance;

and we must fay,

That the changing force is that which will produce in a quiescent body the motion which, by composition with the former motion of a body, will produce the new motion.

And, on the other hand,

When the motion of a body is changed by the action of any force, the new motion is that which is compounded of the former motion, and of the motion which the force would produce in a quiescent body.

When a force changes the direction of a motion, we Secon fee that its direction is transverse in some angle BAC; of M because a diagonal Al) always supposes two sides. As Deflet we have diftinguished any change of direction by the force. term DEFLECTION, we may call the transverse force a DEFLECTING FORCE.

In this way of estimating a change of motion, all the characters of both motions are preserved, and it expresses every circumstance of the change; the mere change of direction, or the angle BAD, is not enough, because the same force will make different angles of deflection, according to the velocity of the former motion, or according to its direction: but in this estimation, the full effect of the deflecting force is feen; it is feen as a motion; for when half of the time is elapsed, the body is at e instead of E; when three-fourths are elapsed, it is at finstead of F; and at the end of the time it is at D initead of B. In short, the body has moved uniformly away from the points at which it would have arrived independent of the change; and this motion has been in the same direction, and at the same rate, as if it had moved from A to C by the changing force alone. Each force has produced its full effect; for when the body is at D, it is as far from AC as if the force AC had not acted on it; and it is as far from AB as it would have been by the action of AC alone.

For all these reasons, therefore, it is evident, that if we are to abide by our measure and character of force as a mere producer of motion, we have felected the proper characteristic and measure of a changing force: and our descriptions, in conformity to this selection, must be agreeable to the phenomena of nature, and retain the accuracy of geometrical procedure; because, on the other hand, the results which we deduce from the supposed influence of those forces are formed in the same mould. It is not even requifite that the real exertions of the natural forces, such as pressure of various kinds, &c. shall follow these rules; for their deviations will be confidered as new forces, although they are only indications of the differences of the real forces from our hypothesis. We have obtained the precious advantage of mathematical investigation, by which we can examine the law of exertion which characteriles every force in nature.

On these principles we establish the following fundamental elementary proposition, of continual and indifpensable use in all mechanical enquiries.

If a body or material particle be subjected at the same time Funda to the action of two moving forces, each of which tal the war awould separately cause it to describe the side of a parallelogram uniformly in a given time, the body will describe the diagonal uniformly in the same time.

For the body, whose motion AB was changed into AD, had gotten its motion by the action of some force. It was moving along NAB; and, when it reached the point A, the force AC acted on it. The primitive motion is the same, or the body is in the same condition in every instant of the primitive motion. It may have acquired this motion when it was in N, or when at O, or any other point of NA. In all these cases, if AC act on it when it is in A, it will always describe AD; therefore it will describe AD when it acquires the primitive motion also in A; that is, if the two forces act on it at one and the same instant. The demonfiration may be neatly expressed thus: The change in-

14s mark and meafure.

Changing force.

Its effect.

indian duced by each force on the motion produced by the Motion other, is the motion which it would produce in the body if previously at rest. Therefore the motion resulting from joint action is the motion which is compounded of these two motions; or it is a motion in the diagonal of the parallelogram, of which these motions are the sides.

This is called the Composition of Forces. The

This is called the Composition of Forces. The forces which produce the motions along the fides of the parallelogram are called the Simple Porces, or the Constituent Forces; and the force which would alone produce the motion along the diagonal is called the Compound Force, the Resulting Force, the Equivalent Force.

On the other hand, the force which produces a motion along any line whatever, may be conceived as refulting from the combined action of two or more forces. We may know or observe it to be so; as when we see a lighter dragged along a canal by two horses, one on each side. Each pulls the boat directly toward himself in the direction of the track-rope; the boat cannot go both ways, and its real motion, whatever it is, results from this combined action. This might be produced by a single force; for example, if the lighter be dragged along the canal by a rope from another lighter which precedes it, being dragged by one horse, aided by the helm of the foremost lighter. Here the real force is not the resulting, or the compound, but the equivalent force.

This view of a motion, mechanically produced, is called the RESOLUTION OF FORCES. The force in the diagonal is faid to be refolved into the two forces, having the directions and velocities reprefented by the fides. This practice is of the most extensive and multifareous use in all mechanical disquisitions. It may frequently be exceedingly difficult to manage the complication of the many real forces which concur in producing a phenomenon; and by substituting others, whose combined effects are equivalent, our investigation may be much expedited. But more of this afterwards.

We must carefully remember, that when the motion AD is once begun, all composition is at an end, and the motion is a simple motion. The two determinations, by one of which the body would describe AB, and by the other of which it would describe AC, no longer co-exist in the body. This was the case only in the instant, in the very act of changing the motion AB into the motion BD; yet is the motion AD equivalent to a motion which is produced by the actual composition of two motions AB and AC; in which case the two motions co-exist in every point of AD.

Accordingly this is the way in which the composition of forces is usually illustrated, and thought to be demonstrated. A man is supposed (for instance) to walk uniformly from A to C on a sheet of ice, while the icc is carried uniformly along AB by the stream. The man's real motion is undoubtedly along AD; but this is by no means a demonstration that the instantaneous or short lived action of two forces would produce that motion; the man must continue to exert force in order to walk, and the ice is dragged along by the stream. Some indeed express this proof in another way, saying, let a body describe AB, while the space in which this motion is performed is carried along AC. The ice may be carried along, and may, by friction, or otherwise, drag the man along with it; but a space

cannot be removed from one place to another, nor, if SecondLaw it could, would it take the man with it. Should a of Motions thip start suddenly forward while a man is walking across the deck, he would be left behind, and fall toward the stern. We must suppose a transverse force, and we must suppose the composition of this force without proof. This is no demonstration.

We apprehend, that the demonstration given above of this fundamental proposition is unexceptionable, when the terms force and deflection are used in the abstract sense which we have affixed to them; and we hope, by these means, to maintain the rigour of mathematical discussion in all our suture disquisitions on these subjects. The only circumstance in it which can be the subject of discussion is, whether we have selected the proper measure and characteristic of a change of motion—We never met with any objection to it.

But some have still maintained, that it does not evi-Objections dently appear, from these principles, that the motion to the dewhich refults from the joint action of two natural monftration powers, whose known and measurable intensities have it will not the same proportions with AB and BC, and which also apply to exert themselves in those directions, will produce a mo-pressures. tion, having the direction and proportion of AD. They will not, if the velocities produced by these forces are not in the proportion of those intensities, but in the subduplicate ratio of them. Nay, they say, that it is not fo. If a body be impelled along AC by one fpring, and along AB by two fprings equally ffrong, it will not describe the diagonal of a parallelogram, of which the fide AB is double the fide AC. Nay, they add, that an indefinite number of examples can be given where a body does not describe the diagonal of the parallelogram by the joint action of two forces, which, feparately, would cause it to describe the sides. And, laitly, they fay, that, at any rate, it does not appear evident to the mind, that two incitements to motion, having the directions and the same proportion of intensity with that of the fides of a parallelogram, actually generate a third, which is the immediate cause of the motion in the diagonal. An equivalent force is not the fame with a refulting force.

Yet we see numberless cases of the composition of incitements to motion, and they feem as determinate, and as susceptible of being combined by composition, as the things called moving forces, which are measured by the velocities: we fee them actually fo combined in a thousand instances, as in the example already given of a lighter dragged by two horses pulling in different directions. Nay, experiment shews, that this compofition follows precifely the fame rule as the composition of the forces which are measured by the velocities; for if the point A (fig. 1.) be pulled by a thread, or preffed by a spring, in the direction AB, and by another in the direction AC, and if the pressures are proportional to AB and AC, then it will be withheld from moving, if it be pulled or pressed by a third force, acting in the direction Ad, opposite to AD, the pressure being also proportional to AD. This force, acting in the direction Ad, would certainly withstand an equal force acting in the direction AD; therefore we must conclude, that the two pressures AB and AC really generate a force AD. This uniform agreement shews that the composition is deducible from fixed principles; but it does not appear that it can be held as demon-

3 T 2

ftrated

49

SecondLaw strated by the arguments employed in the case of moof Motion tions. A demonstration of the composition of preffures is still wanted, in order to render mechanics a demonstrative science.

Accordingly, philosophers of the first eminence have position is turned their attention to this problem. It is by no or more dir-means easy; being so nearly allied to first principles, that it must be difficult to find axioms of greater simplicity

by which it may be proved.

Mechanicians generally contented themselves with the folution given by Aristotle; but this is merely a composition of motions: indeed he does not give it for any thing elfe, and calls it " συνθεσις των φυ αν." The first writer who appears to have confidered it as different from the mere composition of motions, was the celebrated Dutch engineer Stevinus in his work on Sluices; but his folution is obscure. It was sufficient, however, to convince Daniel Bernoulli of the necessity and the difficulty of the problem. He has given the first complete demonstration of it in the first volume of the Commentaries of the Imperial Academy of Sciences at St Petersburgh. It is extremely ingenious; but it is tedious and intricate, requiring a feries of 15 propositions to demonstrate that two pressures, having the directions and magnitudes of the fides of any parallelogram, compose a third, which has the direction and magnitude of its diagonal. His first proposition is, that two equal pressures, ading at right angles, compose a third, in the direction of the diagonal of a square, and having to either of the other two the proportion of the diagonal of a Square to its fides.

Mr D'Alembert has greatly simplified and improved this demonstration, by beginning with a case that is selfevident; namely, If three equal forces are inclined to each other in equal angles of 120 degrees, any one of them will balance the combined action of the other two. Surely; for neither of them can prevail. Therefore two equal forces, inclined in an angle of 120 degrees, produce a third, which has the direction and proportion of the diagonal of the rhombus; for this is equal and oppofite to one of the three above mentioned. He then demonstrates the same thing of two equal forces inclined in any angle; and by a feries of eight propositions more, demonstrates the general theorem. This differtation is in the Memoirs of the Academy at Paris for 1769. He improves it still farther in a subsequent memoir.

Mr Riccati and Mr Fonfenex, in the Commentaries of the Academy of Turin, have given analytical demonflrations, which are also very ingenious and concise, but require acquaintance with the higher mathematics. -There is another very ingenious demonstration in the Tournal des Scavans for June 1764, but too obscure for an elementary proposition. It is somewhat simplified by Belidor in his Ingenieur François. Frifius, in his Cosmographia, has given one, which is perhaps the best of all those that are easily comprehended without acquaintance with the higher mathematics: but we imagine that, although no one can doubt of the conclufion, it has not that intuitive evidence for every step of

the process that seems necessary.

We here offer another, composed by blending togeof pressures ther the methods of Bernoulli and D'Alembert; and we imagine that no objection can be made to any step of it. We limit it entirely to pressures, and do not at

all confider nor employ the motions which they may be Suco supposed to produce.

(A) If two equal and opposite pressures or incitements to motion act at once on a material particle, it suffers no change of motion; for if it yields in either direction by their joint action, one of the pressures prevails, and they are not equal.

Equal and opposite pressures are said to BALANCE each other; and fuch as balance must be esteemed equal

and opposite.

(B) If a and b are two magnitudes of the same kind, proportional to the intensities of two pressures which act in the same direction, then the magnitude a + b will measure the intensity of the pressure, which is equivalent, and may be called equal, to the combined effort of the other two; for when we try to form a notion of preffure as a measurable magnitude, distinct from motion or any other effect of it, we find nothing that we can meafure it by but another preflire. Nor have we any notion of a double or triple pressure different from a presfure that is equivalent to the joint effort of two or three equal preffures. A preffure a is accounted triple of a pressure b, if it balances three pressures, each equal to b, acting together. Therefore, in all proportions which can be expressed by numbers, we must acknowledge the legitimacy of this meafurement; and it would furely be affectation to omit those which the mathematicians call incommensurable.

In like manner, the magnitude a - b must be acknowledged to measure that pressure which arises from the joint action of two preffures a and b acting in oppo-

fite directions, of which a is the greatest.

(C) Let ABCD and A b C d (fig. A) be two rhombuses, which have the common diagonal AC. Let the angles BAb, DAd, be bisected by the straight lines AE and AF.

If there be drawn from the points E and F the lines EG, EH, Fg, Fh, making equal angles on each fide of EA and FA, and if Gg, Hb be drawn, cutting the diagonal AC in I and L: then AI + AL will be greater or less than AQ, the half of AC, according as the angles GEH, gFh, are greater or less than GAH,

Draw GH, gh, cutting AE, AF, in O and o, and

draw Oo, cutting AC in K.

Because the angles AEG and EAG are respectively equal to AEH and EAH, and AE is common to both triangles, the fides AG, GE are respectively equal to AH, HE, and GH is perpendicular to AE, and is bisected in O; for the same reasons, gh is bisected in Therefore the lines Gg, Oo, Hb, are parallel, and IL is bisected in K Therefore AI + AL is equal to. twice AK. Moreover, if the angle GEH be greater than GAH, AO is greater than EO, and AK is greater than KQ. Therefore AI + AL is greater than AQ; and if the angle GEH be less than GAH, AI + AL is less than AQ.

(D) Two equal preffures, acting in the directions AB and AC (fig. 2.), at right angles to each other, compose a pressure in the direction AD, which bisects the right angle; and its intenfity is to the intenfity of each of the constituent pressures as the diagonal of a fquare to one of the fides. It is evident, that the direction of the pressure, generated by their joint action,

Composition

conditaw will bisect the angle formed by their directious; because Motion no reason can be affigned for the direction inclining

more to one fide than to the other.

In the next place, fince a force in the direction AD does, in fact, arise from the joint action of the equal pressures AB and AC, the pressure AB may be conceived as arising from the joint action of two equal forces fimilarly inclined and proportioned to it. Draw EAF perpendicular to AD. One of these forces must be directed along AD, and the other along AE. In like manner, the pressure AC may arise from the joint ac. tion of a preffure in the direction AD, and an equal pressure in the direction AF. It is also plain, that the preflures in the directions AE and AF, and the two pressures in the direction AD, must be all equal. And also, any one of them must have the same proportion to AB or to AC, that AB or AC has to the force in the direction AD, arising from their joint action.

Therefore, if it be faid that AD does not measure the pressure arising from the joint action of AB and AC, let A d, greater than AD, be its just measure, and make Ad: AB = AB: Ag = AB: Ae. Then Ag and Ae have the same inclination and proportion to AB that AB and AC have to A d. We determine, in like manner, two forces Af and Ag as constituents

Now A d is equivalent to AB and AC, and AB is equivalent to Ae and Ag; and AC is equivalent to Af and Ag. Therefore Ad is equivalent to Ae, Af, Ag, and Ag. But (A) Ar and Af balance each other, or annihilate each other's effect; and there remain only the two forces or pressures Ag, Ag. Therefore (B) their measure is a magnitude equal to twice Ag. But if Ad be greater than the diagonal AD of the square, whose sides are AB and AC; then A g must be less than AI, the side of the square whose diagonal is AB. But twice Ag is lefs than AD, and much less than A d. Therefore the measure of the convalent of AB and AC cannot be a line A d greater than AD. In like manner, it cannot be a line As that is less than AD. Therefore it must be equal to AD, and the proposition is demonstrated.

(E) Cor. Two equal forces AB, AC, acting at right angles, will be balanced by a force AO, equal and opposite to AD. the diagonal of the square whose fides are AB and AC; for AO would balance AD,

which is the equivalent of AB and AC.

(F) Let AECF (fig. 3.) be a rhombus, the acute angle of which EAF is half of a right angle. Two equal pressures, which have the directions and measures AE, AF, compose a pressure, having the direction and measure AC, which is the diagonal of the rhombus.

It is evident, in the first place, that the compound force has the direction AC, which bifects the angle EAF. If AC be not its just measure, let it be AP less than AC. Let ABCD be a square described on the fame diagonal, and make AP : AQ = AE : AO, = AF : Ao. Draw KOG, Kog perpendicular to AE, AF; draw GIg, OHo, EG, EK, Fg, FK, PF, and PE.

The angles CAB and FAE are equal, each being half of a right angle. Also the figures AEPF and AGEK are fimilar, because AP : AQ = AE : AO. Therefore FA: AP = KA: AE, and EA: AP = GA: AE. Therefore, in the same manner that the forces AE, AF are affirmed to compose AP, the forces SecondLaw AG and AK may compose the force AE, and the forces of Motion. Ag and AK may compose the force AF. Therefore (B) the force AP is equivalent to the four forces AG, AK, Ag, AK. But (D) AG and Ag are the fides of a square, whose diagonal is equal to twice AI: and the two forces AK, AK are equal to, or are mea-fured by, twice AK. Therefore the four forces AG, AK, Ag, AK, are equivalent to 2 AI + 2 AK, == 4 AH.

But because AP was supposed less than AC, the angle FPE is greater than FAE, and GEK is greater than GAK, AO is greater than OE, and AH is greater than HQ, and 2 AH is greater than AQ; and therefore 4 AH is greater than AC, and much greater than AP. Therefore AP is not the just measure of

the force composed of AE and AF.

In like manner, it is shewn, that AE and AF do not compose a force whose measure is greater than AC. It is therefore equal to AC; and the proposition is de-

monstrated.

(G) By the same process it may be demonstrated, that if BAD be half a right angle, and EAF be the fourth of a right angle, two forces AE, AF will compose a force measured by AC. And the process may be repeated for a rhombus whose acute angle is 1th, 17th, &c. of a right angle; that is, any portion of a right angle that is produced by continual bifection. Two forces, forming the fides of fuch a rhombus, compose a force measured by the diagonal.

(H) Let ABCD, Abcd (fig. 4.) be two rhombutes formed by two confecutive bifections of a right angle. Let AECF be another rhombus, whose fides AE and AF bifect the angles BA b and DA d.

The two forces AE, AF, compose a force AC. Bisect AE and AF in O and o. Draw the perpendiculars GOH, gob, and the lines GIg, OKo, HLb,

and the lines EG, EH, Fg, Fb.

It is evident, that AGEH and Ag Fb are shombuses; because AO = OE, and Ao = oF. It is also plain, that fince bAd is half of BAD, the angle GAH is half of b A d. It is therefore formed by a continual bisection of a right angle. Therefore (G) the forces AG, AH, compose a force AE; and Ag, Ab, compose the force AF. Therefore the forces AG, AH, A g, A h, acting together, are equivalent to the forces AE, AF acting together. But AG, Ag compose a force = 2 Al; and the forces AH, Ab compose a force = 2 AL. Therefore the four forces acting together are equivalent to 2 AI + 2 AI, or to 4 AK. But because AO is 1 AE, and the lines Gg, Oo, Hb, are evidently parallel, 4 AK is equal to 2 AQ, or to AC; and the proposition is demonstrated.

(I) Cor. Let us now suppose, that by continual bifection of a right angle we have obtained a very small angle a of a rhombus; and let us name the rhombus by

the multiple of a which forms its acute angle.

The proposition (G) is true of a, 2 a, 4 a, &c. The proposition (H) is true of 3 a. In like manner, because (G) is true of 4 a and 8 a, proposition (H) is true of 6 a; and because it is true of 4 a, 6 a, and 8 a, it is true of 5 a and 7 a. And fo on continually till we have demonstrated it of every multiple of a that is less than a right angle.

(K) Let RAS (fig. 5.) be perpendicular to AC,

3 condlaw and let ABCD be a thombus, whose acute angle BAD of, Motion is fome multiple of 2 a that is less than a right angle. Let A b c d be another rhombus, whose fides A b, A d bisect the angles RAB, SAD. Then the forces A b, A d compole a force AC

Draw bR, dS parallel to BA, DA. It is evident, that AR b B and AS d D are rhombuses, whose acute angles are multiples of a, that are each less than a right angle. Therefore (I) the forces AR and AB compose the force A b, and AS, AD compose A d; but AR and AS annihilate each other's effect, and there remains only the forces AB, AD. Therefore A b and A d are equivalent to AB and AD, which compose the force AC; and the proposition is demonstrated.

(I.) Cor. Thus is the corrollary of last proposition extended to every rhombus, whose angle at A is some multiple of a less than two right angles. And fince a may be taken less than any angle that can be named, the proposition may be considered as demonstrated of

every rhombus: and we may fay,

(M) Two equal forces, inclined to each other in any angle, compose a force which is measured by the diagonal of the rhombus, whose sides are the measures of the constiuent forces.

(N) Two forces AB, AC (fig. 6.), having the direction and proportion of the fides of a rectangle, compose a force AD, having the direction and proportion of the diagonal.

Draw the other diagonal CB, and draw EAF pa-

rallel to it; draw BE, CF parallel to DA.

AEBG is a rhombus; and therefore the forces AE and AG compose the force AB. 'AFCG is also a rhombus, and the force AC is equivalent to AF and AG. Therefore the forces AB and AC, acting together, are equivalent to the forces AE, AF, AG, and AG acting together, or to AE, AF, and AD acting together: But AE and AF annihilate each other's action, being opposite and equal (for each is equal to the half of BC). Therefore AB and AC acting together, are equivalent to AD, or compose the force AD.

(O) Two forces, which have the direction and proportions of AB, AC (fig. 7.) the fides of any parallelogram, compose a force, having the direction and pro-

portion of the diagonal AD.

Draw AF perpendicular to BD, and BG and DE

perpendicular to AC.

Composi-

Then AFBG is a rectangle, as is also AFDE; and AG is equal to CE. Therefore (N) AB is equivalent to AF and AG. Therefore AB and AC acting together, are equivalent to AF, AG, and AC acting to. gether; that is, to AF and AE acting together; that is (N) to AD; or the forces AB and AC compose the force AD.

Hence arises the most general proposition,

If a material particle be urged at once by two pressures cion of all or incitements to motion, avhose intensities are proportional incirements to the fides of any parallelogram, and which ad in the dito motion. rections of those sides, it is affected in the same manner as if it were asted on by a fingle force, whose intensity is meafured by the diagonal of the parallelogram, and which acts in its direction: Or, two pressures, having the direction and proportion of the sides of a parallelogram, generate a prefure, having the direction and proportion of the diagonal. Thus have we endeavoured to demonstrate from ab-

Aract principles the perfect fimilarity of the composition

of pressures, and the composition of forces measured by Second the motions which they produce. We cannot help be of Mora ing of the opinion, that a separate demonstration is indispensably necessary. What may be fairly deduced stemis from the one case, cannot always be applied to the different other. No composition of pressures can explain the of the change produced by a deflecting force on a motion al-political ready existing; for the changing pressure is the only of pres one that exists, and there is none to be compounded diappe with it. And, on the other hand, our notions and ob- when fervations of the composition of motions will not explain mined the composition of pressures, unless we take it for granted that the pressures are proportional to the velocities; but this is perhaps a gratuitous assumption. At any rate, it is not an intuitive propolition; and we have mentioned some facts where it seems that they do not follow the fame proportion. The pressure of four equal fprings, produces only a double velocity. It would appear, therefore, that there are circumstances which oblige us to fay, that the exertion of preffure, as a cause of motion, is not (always at least) proportional to the real measurable pressure. We are therefore anxious to discover in what the difference confilts; and in the mean time must allow, that the pressure exerted on a body at rest is different from its exertion in producing motion. We cannot indeed state any immediate comparison between pressure and motion, nor have we any clear conception of the connection between them. It is only by our sensations of touch that we have any notion of preffure, and it is experience that teaches us that it always accompanies every cause of motion. We can, however, observe the proportions of pressures, and compare them. with the proportions of motion. We very often ob. ferve them different; and therefore it was indifpenfably necessary to investigate the laws of combined pressure as we did the laws of combined motion in confequence of pressure. Yet we should err, if we hastily afferted that pressures are not proportional to the motions which they produce; all that we are intitled to call in doubt is, whether the pressures in their exertion, while they actually produce motion, or changes of motion, continue to be the fame as when they do not produce motion, being withstood or balanced by opposite pref-Confidered as causes of motion, we ought to think that they do not vary while they produce motion, and that the actual pressure, while it produces a double motion, is really double, although it may be quadruple when the body exerting it is made to act on a body that it cannot move. We are confirmed in this opinion by observing, that other facts shew us, that even while producing motion, the preffure which we call quadruple, because we have measured it by four equal preffures balancing it, is really quadruple, confidered as the cause of motion, and produces a quadruple motion. A bow which requires four times the force to draw it to any given extent, will communicate the same velocity to a bundle of four arrows that a bow four times easier drawn communicates to one arrow, and will therefore produce a quadruple motion. Yet it will only produce a double velocity in the arrow that acquired a simple velocity from a bow having one fourth of the strength.

These discrepancies should excite the endeavours of mechanicians to investigate the laws observed in the action of pressures in producing motion. Had this been done with care and with candour, we should not have

condLaw had the great difference of opinion, which still divides Motion philosophers, about the measures of moving forces. But a spirit of party, which had arisen from other causes, gave importance to what was at first only a difference of expression, and made the partisans of Mr Leibnitz avail themselves of the figurative language which has done so much harm in all the departments of philosophy. Notwithstanding all our caution, it is hardly posfible to avoid metaphorical conceptions when we employ the language of metaphor. The abettors of the Leibnitzian measure of moving forces, or perhaps, to fpeak more properly, the abettors of the Leibnitzian measure of that force which is supposed to preserve bodies in their condition of motion-infift, that the force which is exerted in producing any change of motion is greater in proportion as the motion changed is greater: and they give a very specious argument for their affertion. They appeal to the exertions which we our-felves make. Here we are conscious of the fact. Then they give fimilar examples of the action of bodies. A clay ball, moving fix feet per fecond, will make the addition of one foot to the velocity of an equal clay ball that is already moving four feet per fecond in the same direction. But if this last ball be already moving ten feet per fecond, we must follow it with a velocity of twelve feet in order to increase its velocity one foot. But, without infifting on the numberless paralogisms and inconfishencies which this way of conceiving the matter would lead us into, it fuffices to observe, that the phenomena give us abundant affurance that there has been the same exertion in both these cases. acceleration is always accompanied by a compression of the balls, and the compression is the same in both. This compression is a very good measure of the force employed to produce it; and in the present case, we need not even trouble ourselves with any rule for its measure. ment: for furely when the compression is not different, but the same, the force exerted is the same. This is farther confirmed by observing, that it requires the same force to make the fame pit, or to give the fame mo-tion, to a piece of clay lying on the table of a ship's cabin, whether the ship be failing two miles or ten miles per hour.

Thus we see that there are strong reasons for believing, that the exertions of preflure in producing motion, or that the pressures actually exerted, are proportional to the changes of motion observed, and that they coincide in this refpect with our abstract conceptions of moving forces.

But we have still better arguments. None of the Leibnitzians think of denying the equal exertions of gravity, or of any of those powers which they call folicitations or accelerating forces. They all admit, that gravity, or any constant accelerating force, produces equal increments of velocity in equal times, and that a double gravity will produce a double increment in an equal time, and an equal increment in half of the time; and that a quadruple gravity will produce a double velocity in half the time. All these things are granted by them, and their writings are full of reasonings from this principle. Now from the fact, acknowledged by the Leibnitzians, that the quadruple force of a bow gives a double velocity to the arrow, in every instant of its action, it indisputably follows, that it has acted on it only for half the time of the action of the four

times weaker bow, which gives the arrow only half the SecondLaw velocity; and thus has the discrepancy between the ef-of Motion. fects of pressures and of our abstract moving forces entirely disappeared. For this circumstance of the difference in the time of acting will be found, on strict examination, in all the cases of the change of motion by pressures which we measure by their effects on a body at rest. When this and the appreciable changes of actual pressure, during the time of producing the motion, are taken into confideration, all difference vanishes, and the composition of pressures is in perfect harmony with the composition of motions, or of abstract moving forces. DYNAMICS is thus made a demonstrative science, and affords the opportunity of investigating, by observation and experiment, the nature of those mechanical powers which refide in bodies, and which appear to us under the form of pressure, inducing us to consider presfure as a cause of motion.

In this, however, we are rather inaccurate. Pressure is one of the fensible effects of that property which is also the cause of motion. It is not the pressure of a piece of lead, but its heaviness, that is the reason that it gives motion to a kitchen jack. Pressure is merely a generic name, borrowed from a familiar instance, and given to moving forces, which have the same nature, but different names that ferve to mark their connection with certain fubstances, in which they may be supposed to refide. Natural philosophy is almost entirely employed in examining the nature of these various prefforces or accelerative forces; and the general doctrines of dynamics, by afcertaining what is common to them all, enable us to mark with precision what is characteriftie of each.

We have now advanced very far in this investigation; General cofor we have obtained the criterion by which we learn rollaries. the direction and the magnitude of every changing force: and, on the other hand, we fee how to state what will be the effect of the exertion of any force that is known or suspected to act. All this we learn by the composition of forces; and the greatest part of mechanical disquisition confits in the application of this doctrine. For fuch reasons it merits minute confideration; and therefore we must point out some general conclusious from the properties of figure, which will greatly facilitate the use of the parallelogram of forces.

1. The constituent and the refulting forces, or the fimple and compound forces, act in the same plane; for the fides and diagonal of a parallelogram are in one

2. The simple and the compound forces are proportional to the fides of any triangle which are parallel to their directions. For if any three lines, ab, bd, ad, be drawn parallel to AB, AC, and AD (fig. 7, nº 2.), they will form a triangle fimilar to the triangle ABD. For the fame reasons they are proportional to the fides of a triangle d'Ud, which are respectively perpendicular to their directions.

3. Therefore each is proportional to the fine of the opposite angle of this triangle; for the fides of any triangle are proportional to the fines of the opposite angles.

4. Each is proportional to the fine of the angle contained by the directions of the other two; for A'D is to AB as the fine of the angle ABD to the fine of the angle ADB. Now the fine of ABD is the same

54]

37

SecondLaw with the fine of BAC contained between the directions of Motion AB and AC, and the fine of ADB is the fame with the fine of CAD; also AB is to AC, or BD, as the

fine of ADB (or CAD) to the fine of BAD. We now proceed to the application of this fundacial uses of mental proposition. And we observe, in the sixth place, the parallelogram of that fince AD may be the diagonal of an indefinite number of parallelograms, the motion or the pressure AD may refult from the joint action of many pairs of forces. It may be produced by forces which would separately produce the motions AF and AG. generally gives us the means of discovering, the forces

which concur in its production. If one of them, AB, is known in direction and intensity, the direction AC, parallel to BD, and the intenfity, are discovered. Sometimes we know the directions of both. Then, by drawing the parallelogram or triangle, we learn their proportions. The force which deflects any motion AB into a motion AD, is thad by fimply drawing a line from the point B (to which the body would have moved from A in the time of really moving from A to D) to the point D. The deflecting force is fuch as would have gaused the body move from B to D in the same time. And, in the fame manner, we get the compound motion AD, which arises from any two supple motions AB and AC, by supposing both of the motions to be accomplished in succession. The final place of the bo-

dy is the fame, whether it moves along AD or along AB and BD in fuccession.

Equivalent of many

This theorem is not limited to the composition of two motions or two forces only; for fince the combired action of two forces puts the body into the fame flare as if their equivalent alone had acted on it, we may suppose this to have been the case, and then the action of a third force will produce a change on this equivalent motion. The refulting motion will be the same as if only this third force and the equivalent of the other two had acted on the body. Thus, in PlateXX:I. fig. 8. the three forces AB, AC, AE, may act at once

on a particle of matter. Complete the parallelogram ABDC; the diagonal AD is the force which is generated by AB and AC. Complete the parallelogram AEFD; the diagonal AF is the force refulting from the combined action of the forces AB, AC, and AE. In like manner, completing the parallelogram AGHF, the diagonal AH is the force resulting from the combined action of AB, AC, AE, and AG, and so on of

any number of forces.

This refulting force and the refulting motion may be much more expeditionfly determined, in any degree of composition, by drawing lines in the proportion and direction of the forces in fuccession, each from the end of the preceding. Thus, draw AB, BD, DF, FH, and join AH; AH is the refulting force. The de-

monttration is evident.

It is to be noticed here, that in the composition of more than two forces, we are not limited to one plane. The force AD is in the fame plane with AB and AC; but AE may be elevated above this plane, and AG may lead below it. AF is in the plane of AI) and AE, and AH is in the plane of AF and AG.

Complete the parallelograms ABLE, ACKE, ELFK. It is evident that ABLFKCD is a parallelopiped, and that AF is one of its diagonals. Hence

we derive a more general theorem of great use.

Three forces having the proportion and direction of the Secon three sides of a parallelopiped, combose a force baving of h the proportion and direction of the diagonal.

Any number of forces acting together on one par, One ticle of matter are balanced by a force that is equal and may opposite to their resulting force; for this force would ba-lance lance their resulting force which is equivalent to them in action. When this is duly confidered, we perceive that each force is then in equilibrio with the equivalent of all the others; for a force can balance only what is equal and opposite to it. It appears very readily by the geometrical construction. If, instead of the circuit A, B, D, F, H, we take B, D, F, H, A, we have BA for the equivalent of the forces AC, AE, AG; but AB is equal and opposite to BA. Therefore the force AB is in equilibrio with the equivalent of all the others.

When any number of forces act on one particle of matter, and are in equilibrio, if they be considered as acting in parcels, the equivalents of these parcels are in equilibrio; for let the forces AB, AC, AE, AG, Ab, be in equilibrio, and let them be confidered in the two parcels AB, AC, and AE, AG, Ab; then AD is the equivalent of AB, BD (or AC), and DA is the equivalent of DF, FH, HA (or Ab): now AD and DA balance each other. This corollary enables us to fimplify many intricate complications of force; it also enables us to draw accurate conclutions from very imperfect observations. In most of our practical discussions we know, or at least we attend to, a part only of the forces which are acting on a material particle; and in fuch cases we reason as if we saw the whole: yet is our mathematical reasoning good with respect to the equivalent of all the parcels which we are contemplating, and the equivalents of the fmaller parcels of which it confifts; and the neglected force, or parcel of forces,

induces no error on our conclusions.

In the spontaneous phenomena of nature, the investi Exp gation and discovery of our ultimate object of fearch is met frequently very difficult, on account of the multiplicity the of directions and intentities of the operating forces or ing motions. We may generally facilitate the process, by in c fubilituting equivalent forces or motions acting in con- cate a venient directions. It is in this way that the navigator computes the ship's place with very little trouble, by fubilituting equivalent motions in the meridional and equatoreal directions for the real oblique courses of the ship. Instead of setting down ten miles on a course, S. 36. 52. W. he supposes that the ship has failed eight miles due fouth, and fix miles due west, which brings her near to the same place. Then, instead of fourteen miles south-west, he sets down ten miles fouth and ten miles west; and he proceeds in the same way for every other course and distance. He does this expeditiously by means of a traverfe table, in which are ready calculated the meridional and equatoreal fides of right angled triangles, corresponding to every courfe and distance. Having done this for the course of a whole day, he adds all the southings into one fum, and all the westings into another: he considers these as forming the fides of a right angled triangle; he looks for them, paired together, in his traverse table, and then notices what angle and what distance corresponds to this pair. This gives him the position and magnitude of the straight line joining the beginning and end of his day's work. The

60

condiaw The miner proceeds in the same way when he takes Motion the plan of fubterraneous workings, meafuring, as he goes along, and noticing the bearing of each line by the compass, and setting down, from his traverse table, the northing or fouthing, and the eafling or westing, for each oblique line: but there is another circumstance which he must attend to, namely, the slope of the various drifts, galleries, and other workings. This he does by noting the rife or the dip of each floping line. He adds all these into two sums, and taking the risings from the dips, he obtains the whole dip. Thus he learns how far the working's proceed to the north, how far to the east, and how far to the dip.

The reflecting reader will perceive that the line joining the two extremities of this progression will form the diagonal of a rectangular parallelopiped; one of whose sides lies north and south, the other lies east and

west, and the third is right up and down.

The mechanician proceeds in the very fame way in the investigation of the very complicated phenomena which frequently engage his attention. He confiders every motion as compounded of three motions in fome convenient directions, at right angles to each other. He also confiders every force as resulting from the joint action of three forces, at right angles to each other, and takes the fum or difference of these in the fame or opposite directions. From this process he obtains the three fides of a parallelopiped, and from thefe computes the position and magnitude of the diagonal. This is the motion or force refulting from the composition of all the partial ones. orces may

This procedure is called the Estimation or RE-

estima-DUCTION of motions and forces. d by, or

A motion or force AB (fig. 9.) is faid to be effi-mated in the direction EF, or to be reduced to this diduced to, given di-rection when it is conceived as compounded of the motions or forces AC, AD, one of which AC is parallel to EF, and the other AD is perpendicular to it. This expression is abundantly fignificant; for it is plain that the motion AD neither promotes nor hinders the progress along EF, and that AC expresses the whole

progress in this direction.

In like manner, a force AB (fig. 10.) is faid to be r a given estimated in, or reduced to, a given plane EFGH, when it is conceived as refulting from the joint action of two forces AC, AD, one of which is parallel to a line ab drawn in that plane, and the other AD is perpendienlar to it. The position of the line a b is determined by letting fall B b perpendicular to the plane, and drawing b P to the point P, in which BA meets the plane; then A a being drawn parallel to B b, will cut off b a, which is the reduction of the motion AB to the plane. Drawing AC parallel to ab, and completing the parallelogram ACBD, it is evident that the motion AB is equivalent to AD and AC, which is parallel to ab, and the three forces AB, AC, AD, are, as they should be, in one plane perpendicular to the plane EG.

If three forces AB, AC, AD (fig. 11.), are in n of for- equilibrio, and are reduced to any one direction dA l, or to one plane EFGH, the reduced forces are also in

First, Let them be reduced to one direction dl by drawing the perpendiculars B b, Cc, Dd; make AL equal to AD, and join BL, CL, and draw the perpendiculars L1, Cc; then, because the forces AB, AC, SUPPL. VOL. I. Part II.

AD, are in equilibrio, ABLC must be a parallelogram, SecondLaw and AL is the force equivalent to AB and AC com- of Motion. bined; then, because the lines Dd, Bb, Cc, Ll, are parallel, dA is equal to Al, and Ab to Co, or tocl; therefore A l is equal to the fum of A b and A c, which are the reductions of AB and AC; therefore dA is equal to the same sum, and in equilibrio with them.

Secondly, Let them be reduced to one plane EFGH, and let a B, a R, a S, be the reduced forces. The lines D S, A α, B β, C x, L λ, are all parallel, being perpendicular to the plane; therefore the planes AB Ba and CL xx are parallel, and « B, x », are parallel. For fimilar reafone βλ, ακ, are parallel; therefore aβλκ is a parallelograin. Also, because the lines D &, A a, L x, are parallel, and DA is equal to AL; therefore & a is equal to ax. But because about is a parallelogram, the forces ab, ax, are equivalent to ax; and as is equal and opposite to. α », and will balance it; and therefore will balance α β and α », which are the reductions of $\triangle B$ and $\triangle C$ to the plane EFGH, while a s is the reduction of AD; therefore the proposition is demonstrated.

The most usual and the most useful mode of reduc. The most tion, is to estimate all forces in the directions of three useful mode lines drawn from one point, at right angles to each of reducother, like the three plane angles of a rectangular cheft, tion to forming the length, the breadth, and the depth of the dinates. These are commonly called the three co-ordi-The resulting force will be the diagonal of this parallelopiped. This process occurs in all disquisitions in which the mutual action of folids and fluids is confidered, and when the oscillation or rotation of detached

free bodies is the subject of discussion.

The only other general theorem that remains to be Relative deduced from this law of motion is, that if a number motions of of hodies are moving in any manner whatever, and an bodies not equal force act on every particle of matter in the fame affected by any extraor parallel directions, their relative motions will fuffer neous equal no change; for the motion of any body A (fig. 12.), and parallel relative to another body B, which is also in motion, is force. compounded of the real motion of A, and the opposite to the real motion of B; for let A move uniformly from A to C, while B describes BD uniformly, draw AB, also draw AE equal and parallel to BD, join EC, DC, ED. The motion of A, relative to B, confifts in its change of polition and diltance. Had A described AE, while B described BD, there would have been no change of relative place or distance; but A is now at C, and DC is its new direction and diffance. The relative or apparent motion of A therefore is EC. Complete the parallelogram ACFE; it is plain that the motion EC is compounded of EF, which is equal and parallel to AC, the real motion of A, and of EA, the

Now let the motions of A and B sustain the same change; let the equal and parallel motions AG, BH, be compounded with the motions AC and BD; or let forces act at once on A and B, in the parallel directions AG, BH, and with equal intenfities; in either supposition, the resulting motions will be A c, B d, the diagonals of the parallelograms A G c C, and B H d D. Confirmed the figure as before, and we fee that the relative motion is now ec, and that it is the same with

equal and opposite to BD, the real motion of B.

EC both in respect of magnitude and position.

Here we still fee the constant analogy between the composition of motions and the composition of forces.

quilibrinated or duced.

3 U

SecondLaw In the first case, the relative motions of things are not of Motion changed, whatever common motion be compounded with them all; or, as it is usually, but inaccurately, expressed, although the space in which they move be carried along with any motion whatever. In the fecond case, the relative motions and actions are not changed by any external force, however great, when equally exerted on every particle in parallel directions.

Thus it is that the evolutions of a fleet in a uniform current are the same, and produced by the same means, as in still water. Thus it is that we walk about on the furface of this globe in the same manner as if it neither revolved round the fun, nor turned round its axis. Thus it is that the same strength of a bow will communicate a certain velocity to an arrow, whether it is shot east, or west, or north, or south. Thus it is that the mutual actions of fublunary bodies are the fame, in whatever directions they are exerted, and notwithstanding the very great changes in their velocities by reason of the earth's rotation and orbital revolution. The real velocity of a body on the earth's equator is about 3000 feet per fecond greater at midnight than at midday. For at midnight the motion of rotation nearly conspires with the orbital motion, and at midday it nearly oppofes it. The difference between the velocities at the beginning of January and the beginning of July is vaftly greater. And at other times of the day, and other seafons of the year, both motions of the earth are transversely compounded with the easterly or westerly motion of an arrow or cannon bullet. Yet we can observe no change in the effects of the mutual actions of bodies.

This is an important observation; because it proves This affords that forces are to be measured by no other scale than by the motions which they produce. We have had rethe proportionality of peated occasions to mention the very different estimation of moving forces by Mr Leibnitz; and have shewn how, by a very partial confideration of the action of the motions those natural powers called pressures, he has attempted to prove, that moving forces are proportional to the squares of the velocities; and we shewed briefly, in what manner a right confideration of what passes when motion is produced by measurable pressures, proves that the forces really exerted are as the velocities produced. But the most copious proof is had from the present obfervation, that, in fact, the mutual actions of bodies de-

pend on their relative motions alone.

And is incompatible with their those motions.

a demon-

fration of

produced by them,

The Leibnitzian measure of moving force is altogether incompatible with the universal fact now mentioned, viz. that the relative motions of bodies, refulting from ality to the their mutual actions, are not affected by any common squares of motion, or the action of any equal and parallel force on both bodies: for this univerfal fact imports, that when two bodies are moving with equal velocities in the fame direction, a force applied to one of them, fo as to increase its velocity, gives it the same motion relative to the other, as if both bodies had been at rest. Here it is plain, that the space described by the body in consequence of the primitive force, and of the force now added, is the fum of the spaces which each of them would generate in a body at reft. Therefore the forces are proportional to the velocities or changes of motion which they produce, and not to the squares of those velocities. This measure of forces, or the position that a force makes the same change on any velocity whatever, and the independence of the relative motions on any motion that is the same on all the bodies of a system, are counterparts of each other. Since this inde. Seconda pendence is a matter of observation in all terrestrial bo. of M dies, we are intitled to fay, that the powers which the Author of Nature has imparted to natural bodies are no way different from what are competent to matter once called into existence. And it also follows from this, that we must always remain ignorant of the absolute motions of bodies. The fact, that it has required the unremitted fludy of ages to discover even the relative motions of our folar system, is an argument to prove that the influence of this mechanical principle extends far beyond the limits of this fublunary world; nor has any phenomenon yet been exhibited which should lead us to imagine that it is not universal.

When we have made use of these arguments with so Ber fome zealous partizans of Mr Leibnitz's doctrine, they li's de have answered, that if indeed this independence of the of this relative motions of terrestrial bodies were observed to without obtain exactly, it would be a conclusive argument force. But the motion with which all is carried along is fo great in comparison with the motions which we can produce in our experiments, that the small additions or diminutions that we can make to the velocity of this common motion must observe very nearly the proportions of the additions or diminutions of their fquares. The differences of the squares of 2, 3, and 4, are very unequal; but the differences of the squares of 9, 10, 11, are much nearer to the ratio of equality; and the differences of the squares of 1000001, 1000002, 1000003, do not fensibly deviate from this ratio. But it is not fact that we cannot produce motions which have a very fensible proportion to the common motion. The motion of a cannon ball, discharged with one-third of its weight of powder, is nearly equal to that of the rotation of the earth's equator. When, therefore, we discharge the ball eastward, we double its motion; when to the westward, we destroy it. Therefore, according to Leibnitz, the action in the first case is three times the action in the fecond. In the first case it changes the square of the velocity (which we may call 1) from 1 to 4; and, in the fecond, it changes it from 1 to 0. But say the Leibnitzians, the velocity of rotation is but $\frac{1}{63}$ of the orbital velocity of the earth, and our observations of the velocities of cannon bullets are not sufficiently exact to ensure us against an error

But the later observations on the peculiar motions of the fixed flars concur in shewing, that the fun, with his attending planets, are carried along with a very great motion, which, in all probability, has a fensible ratio to the orbital motion of the earth. This must make a prodigious change on the earth's absolute motion, according as her orbital motion conspires with, opposes, or crosses, this other motion: the earth may even be at absolute rest in some points of its orbit. Thus will the composition with the motions produced in our experiments be so varied, that cases must occur when the difference of the refults of the two measures of force will be very fensible.

But, farther, they have not attended to the agreement of our experiments, when the discharges of cannon are made in a direction transverse to that of the common motion. Here the immensity of the common motion, and the minuteness of our experimental velocities, can have no effect in diminishing the difference of the refults of the two doctrines. This will appear dif-

tinctly

and Law tinefly to every reader who is much conversant in dif-Motion quisitions of this kind; and it is in these more moderate motions that the complete independence of the relative motions on the common motions most accurately appears. Pendulum clocks and watches have been often executed which do not deviate from perfect equability of motion one part in 86400. This could not be obtained in all directions of the oscillations, if the forces deviated from the ratio of the velocities one part in 86400.

On the whole, we may consider it as established on the ement of furest foundation, that the action of those powers of naabstract tural bodies which we call pressures, such as the force with of springs, the exertions of animals, the cohesion of bodies, as well as the action of those other incitements to motion which we call attractions and repulfions, fuch as rations gravitation, magnetism, and electricity—is proportional to the change of velocity produced by it. And we must observe here, that this is not a mere mode of conception, the refult of the laws of human thought, which cannot conceive a natural power as the cause of motion otherwife than by its producing motion, and which cannot conceive any degree of moving power different from the degree of the motion. This is the abstract doctrine, and is true whether the pressures are proportional to the velocities or to the squares of the velocities. But we see farther, that whatever is the pressure of a spring (for example) on a quiescent body, yet the pressure actually exerted in producing a double velocity is only double, and not quadruple, as our first imperfect observations make us imagine.

iers.

Sir Isaac Newton has added another proposition to vion's Sir Haac Newton has added another proportion to dlaw of the number of laws of motion; namely, that every acion is tion is accompanied by an equal and contrary reaction. orded on But in affirming this to be a law of nature, lic only e, and means that it is an univerfal fact: And he makes this ot a ne- affirmation on the authority of what he conceives to be a law of human thought; namely, that those qualities which we find in all bodies on which we can make experiments and observations, are to be considered as universal qualities of body. But we have limited the term law of motion to those consequences that necesfarily flow from our notions of motion, of the causes of its production and changes. Now this third Newtonian proposition is not such a result. A magnet is faid to act on a piece of iron when, and only when, the vicinity of the magnet is observed to be accompanied by certain motions of the iron. But it by no means follows from this observation, that the presence of the iron shall be accompanied by any motion, or any change of flate whatever of the magnet, or any appearance that can suggest the notion that the iron acts on the magnet. When this was observed, it was accounted a discovery. Newton discovered, that the sun acts on the planets, and that the earth acts on the moon; and Kepler discovered, that the moon reacts on the earth. Newton had observed, that the iron reacts on the magnet; that the actions of electrified bodies were mutual; and that every action of sublunary bodies was, in fact, accompanied by an equal and contrary reaction. On the authority of his rule of philofophizing he affirmed, that the planets react on the fun, and that the fun is not at rest, but is continually agitated by a small-motion round the general centre of gravitation. He pointed out feveral consequences of this reaction. Aftronomers examined the celeftial motions more narrowly, and found that those confe-SecondLaw quences do really obtain, and disturb all the planetary of Motion. motions. It is now found that this reciprocity of action obtains throughout the folar fystem with the utmost precision, and that the third Newtonian proposition is really a law of nature, although it is not a law of human thought. It is a discovery. The contrary involves no abfurdity or contradiction. It would indeed be contrary to experience; but things might have been otherwife. It is conceivable, and possible, that a ball A shall strike another equal ball B, and carry it along with it, without any diminution of its velocity. The fact, that the velocity of A is reduced to one-half, is the indication of a force reliding in B, which force changes the motion of A; and the intenfity of this force is learned from the change which it produces. This is found to be equal to the change produced by A on B. And thus the reaction of B is discovered to be equal to the action of A.

It is highly probable, that this universality and equality of reaction to action is the confequence of fome general principle, which we may in time discover; meanwhile we are intitled to suppose it universal, and to reason from this topic in our disquisitions about the actions of bodies on each other.

Although the celebrated philosophers of Europe Maupertuhave at last agreed in the reception of the two proposi-is. Leibniz, tions fo largely discussed by us as the laws of motion, and other they have differed exceedingly in their onining about shipsothey have differed exceedingly in their opinion about phers, have their origin and validity: Some afferted that they are emertained entirely matters of experience; while others affirmed very inade-them to be neceffary truths. The royal academy of quare opi-Berlin made this question the subject of their prize diffusions confertation in the year 1744. Mr Maupertuis, president found tion of the academy, published a differtation; in which he of the laws endeavoured to prove that they are necessary truths, only of motion. because they are such as make the quantity of action the least possible, an economy which is worthy of infinite wifdom; and therefore certainly directs the choice of the Author of Nature. On this account alone are they neces-

fary trutlis. But this is not the way to consider a question of this kind. We know too little about infinite wildom to be able to fay with Messrs Leibnitz and Maupertuis, that the Deity should or should not impress on bodies laws different from those which are effential to matter; and we are not to inquire whether God could or could not do this. We know from our own experience, that matter, when subjected to the action of intelligence, may be moved in a way extremely different from what it would follow if left to itself, and that its motions may either be regulated by fixed, but contingent, laws, or may be without any constancy whatever, and vary in every instance. When we suppose the existence of matter and motion, a variety of truths are involved in the supposition, in the same manner as all the theorems in the third book of Euclid's Elements are involved in the conception of a circle and a straight line. Our first employment should be to evolve those truths. We can do this in no way but by first noticing the relations of the ideas that we have of the different objects of contemplation, and then following the laws of human thought in our judgments concerning those relations. This process of the mind is expressed in the train of a geometrical demonstration. The different parts or argu-

Second Law mentations of this train are not the causes of our conof Motion clusions, but the means by which we form our judgement; not the reasons of the truth of our ultimate conclusion, but the steps by which we arrive at the knowledge of it. The young geometer generally thinks otherwise: But that this is the matter of fact is plain from this, that more than one demonstration, and often very different, can be given of the same theorem. We must proceed in the same manner in the present question; and the first general truths which we find involved in the notions of matter, motion, and force, must be received as necessary truths. The steps by which we arrive at the discovery are the laws of human thought; and the expression of the discovery, involving both the truth itself, and the manner of conceiving it, is a necesfary law of motion. There may be other facts, perhaps as general as any of those necessary laws, but which do not necessarily result from the relations of our notions of motion and of force. These are discovered by obfervation only; and they ferve to characterife the forces which nature prefents to our view. These facts are contingent laws of motion.

We apprehend that this method has been followed in treating this article. The first proposition, termed a law of motion, is only a more convenient way of expressing our contemplation of motion in body as an effect of the general cause which we term force. The second proposition does nothing but express more distinctly the relation between this cause and its effect; it expresses what we mean by the magnitude and the kind of the cause. The proposition, stating the composition of forces, is but another form of the same law, better suited to the ordinary procedure in geometrical

disquisitions.

THESE propositions might have completed the doctrines of dynamics; but it appears that, in order to the production of a material universe which should accomplish the purposes of the Creator, it was necessary that there be certain characteristic differences between the forces inherent in the various collections of matter which compose this universe. The facts or physical laws (for the above-mentioned laws are metaphylical) of motion may be different from those which would have been observed had matter been left entirely to itfelf. This difference may have introduced other laws of motion as necessarily resulting from the nature of the forces. We have occasionally mentioned some instances where this appears to obtain, but gave good reafons for affirming, that a due examination of all circumstances which may be observed in the production or variation of motion by those forces, has demonstrated, that there are no fuch deviations from the two laws of motion already determined, but that all the mechanical powers of bodies, when confidered merely as causes of motion, act agreeably to the fame laws. Careful examination was, however, faid to be necessary.

This examination must consist in distinctly noticing the circumstances that occur in the production of motion by any force whatever. It is by no means enough to state simply the intensity of the force and the direction of its exertion. If a force continue to act, it continues to vary the motion already produced. Should the force change its intensity or direction while it is acting, these circumstances must induce still farther

changes in the motion; and it is not till all action has Of A ceased that the motion is brought to its oftensible state, rates in which it is the object of our attention and our far in which it is the object of our attention and our fu- Mot ture discussions. Instances of the effects of such continued and fuch varied actions are to be feen in most of the phenomena of nature or art. The communication of motion by impulse is perhaps the only instance (very frequent indeed) that can be produced where this is not necessary: Nay, we shall perhaps find reason to conclude, that this instance is not an exception, and that even the communication of motion from one billiard ball to another is brought about by an action continued for some time, and greatly varied during that time. Much preparation is therefore necessary before we can apply the general laws of motion to the folution of most of the questions which come before us in the course even of our elementary disquisitions. We must lay down some general propositions which determine the refults of the continued, and perhaps varied, actions of moving forces; and we must mark the different effects of the simple continuation of action, and also those of the variations in this continued action, both in respect of intensity and direction. The effect of a mere continuance of action mult be an acceleration of the motion; or a retardation of it, if the force continue to act in the opposite direction. The effect of the continued action of a transverse force must be a continual deflection, that is, a curvelineal motion. These mult therefore now occupy our attention in their order.

OF ACCELERATED AND RETARDED MOTIONS.

ALL men can perceive, that a stone dropped from Circuit the hand, or sliding down an uniform slope, has its stantiate motion continually accelerated, and that the motion of politic an arrow rifing perpendicularly through the air is con-our co tinually retarded; and they feel no difficulty in concei-condit ving these changes of motion as the effects of the con-of a b tinual operation of their weight or heaviness. The falling in rest stone is in a different condition in respect of motion in to mo the beginning and the end of its fall. In what respect do these states of the body differ? Only in respect to what we call its velocity. 'This is an affection of motion; it is an expression of the relation between the two notions or ideas which concur to form the idea of motion, namely, the space and the time. These are all the circum'tances that we observe in a motion. Time elapses, and during its currency a space is described. The term velocity expresses the magnitude of the space which corresponds to some unit of time. Thus, the rate of a ship's motion is determined, when we say that it is nine miles in an hour, or nine miles per hour. We fometimes fay (but aukwardly) " The motion is at the rate, or with the velocity, of a mile in three days." It is most conveniently expressed by a number of some given units of length, which completely make up the line described during this unit of time. But the mechanicians express it in a way more general by a fraction, of which the numerator is a number of inches, feet, yards, fathoms, or miles, and the denominator is the number of feconds, minutes, or hours, employed in moving along this line. This is a very proper expression; for when we fpeak of any velocity, and continue to reason from it, we conceive ourselves to speak of something that remains the fame, in the different occasions of using the term. Now if the velocity be constant, it is indifferent

h

Accele-how long the line may be; because the time of its dedand scription will be lengthened in the same proportion. Thus if 48 feet be described in 12 seconds, 36 feet will be described in 9 seconds, 16 feet will be described in 4 seconds, &c. Now \(\frac{4}{1}\)\(\frac{8}{5}\), \(\frac{3}{6}\), and \(\frac{16}{4}\), are fractions of equal value, being equal to 4, or 4, that is, to the velocity of 4 feet per second. The value of this fraction, or the quotient of the number of the units of length, divided by the number of units of time, is the number of those units of length described uniformly in one unit of time.

But how shall we determine the velocity in any instant or in any point of a motion that is continually changing? Suppose that a body has fallen 144 feet, and that we no ac-would ascertain its velocity in that point of its fall, or mea- the velocity which it has in passing through that point? In the next fecond the body falls 112 feet farther. This cannot be the measure of the velocity at the beginning of the fourth or the end of the third fecond. It is too great. The fall during the preceding second was 85 feet. This is too small. The mean of these

two, or $\frac{80+112}{2}$, = $\frac{192}{2}$, = 96, is probably more ex-Due attention to the nature of this motion shews

us, that 96 is the proper measure, or that the motion at that instant is at the rate of 96 feet per second. But it is peculiar to this kind of motion that the half fum of the spaces described in two succeeding equal moments is the measure of the velocity in the middle instant. Therefore this method will not generally give an accurate measure. Yet it is indispensably necessary to obtain some accurate measure; for it is in this particular alone that the state of the body differs from its fimilar state in another instant. The difference of place makes no diffinction; for if a body continue its motion unchanged, its condition in every different instant of time, or point of space, is unchanged or the same. The change of place is not a change of motion, but is involved in the very conception of the continuation of the motion. The change of condition confilts, therefore, in the change of velocity: Therefore the change of velocity is the only indication, and the only measure of the action (perhaps accumulated) of the changing force. It is therefore the chief object of our fearch; and accurate measures of velocity are absolutely necessary. When the velocity changes continually, there can be

no adual measure of it. In what then does the magnitude of a velocity confist, when there is no actual meafure of it? It is a certain undescribable DETERMINA-TION; by which, if not changed, a certain space would be uniformly described in a given unit of time. Thus we know, that if, when a stone has fallen 16 feet, its motion be directed along a horizontal plane, without diminution, it will move on for ever at the rate of 72 32 feet per fecond. The space which would be thus menta-ropor- described is not the velocity, but the measure of the veof ve- locity. But the proportions of those spaces, being the ties that proportions of those measures, are the proportions of

conti- the velocities themselves. We may discover these pronging. portions in the following manner: Let ACG (fig. 13.) be a line described by a body equifite with a motion anyhow continually, but gradually, varied; and let it be required to determine the proportion of the velocity in any point C to the velocity in

any other point F.

any ratio less than that of C to D, but less than any ratio Retarded greater than that of C to D, then A is to B as C to D. Motions. Take the fraight line a c g to represent the time of the body's motion along ACG, so that the points a, c,

f, g, may represent the instants of time in which the body passes through the points A, C, F, G; and the portions ac, cf, fg, of the line ag, may represent the times employed in describing the portions AC, CF, FG; and therefore ac is to af as the time of describing AC to the time of describing AF.

Moreover, let bkno be a line fo related to the ftraight line a cfg, by the perpendicular ordinates a h, ck, fn, go, that the areas uckh, afnh, agob, may be proportional to the portions AC, AF, AG, of the line described by the moving body; and let this relation be true with respect to every point B, D, E, &c. and the corresponding points b, d, e, &c.

Then it is affirmed, that the velocity in the point C is

to the velocity in the point F as ck is to fn.

Let the equal lines bc, cd, ef, fg, represent equal moments of time, and let B, D, E, G, be the points through which the body is passing at the instants b, d, Then the areas bike, ckld, emnf, fnog, will represent, and be proportional to, the spaces BC, CD, EF, FG, which are described during the moments bc, cd, ef, fg.

Draw to parallel to ag, so as to make the rectangle bipc equal to the trapezium bikc; and draw the lines q v, ur, sx, in the same manner, so that each rectangle may be equal to its corresponding trapezium.

If the motions had been uniform during the moments bc and fg, that is, if the spaces BC and FG had been uniformly described, then the velocity in the point C would have been to the velocity in the point F as cp to fs: For fince the rectangles b tpc and fsxg are respectively equal to the trapeziums bikc and fnog; and since bike is to fnog as BC is to FG, the rectangle btpe is to the rectangle forg as BC to FG. But because these two rectangles have equal altitudes bc and fg, they are to each other in the proportion of their bases op and gx, or op and fs. Therefore BC is to FG as op to fs. But if BC and FG are uniformly described in equal times, they are proportional to the velocities of those uniform motions. Therefore cp is to fs as the velocity with which BC is uniformly described to the velocity with which FG is uniformly deferibed in an equal time.

But the motion expressed by the figure is not uniform, because the line blo recedes from the axis ag, and the areas, cut off by the parallel ordinates, increase in a greater proportion than the corresponding parts of the axis; that is, the spaces increase faster than the times: for the moments bc, cd, ef, fg, being all equal, it is evident that the corresponding slips of the area continually augment The motion is swifter at the instant c than at the instant b, and the velocity at the instant c. is greater than that with which the space BC would be uniformly described in the same time. For the same reason, the velocity at the instant f is less than that with which the space FG would be uniformly described in the same time. Therefore the velocity at the instant c is to the velocity at the inflant f in a greater ratio than that of cp to fs. In the very same manner, it will appear, by comparing the motion during the moment

Of Accele cd with the motion during the moment ef, that the vetated and locity at the instant c is to the velocity at the instant f Retarded Water at the initial that of eq to fr.

Therefore the velocity in the point C is to the velocity in the point F in a greater ratio than that of cp to

fs, but in a lefs ratio than that of a q to fr.

But by continually diminishing the equal moments bc, cd, ef, fg, it is evident that cp and cq continually approach to equality with ck; and fr and fs continual-'ly approach to equality with f n, that when c p is less than ck, fs is greater than fn, and when cq is greater

than cb, fr is less than fn.

Therefore the velocity in the point C is to the velocity in the point F in a ratio that is greater than the ratio of any line less than ck to any line greater than fn, but which is less than the ratio of any line greater than ck to any line less than fn. Therefore the ratio of the velocity in C to the velocity in F is greater than any ratio that is less than that of ck to fn; but it is less than any ratio that is greater than that of ck to fn. Therefore the velocity in the point C is to the velocity in the point F as ck to fn.

This important theorem may be expressed in more

general terms as follows:

If the abscissa ag of a line hko represent the time of any motion, and if the areas bounded by parallel ordinates be proportional to the spaces described, the ordinates are proportional to the velocities.

REMARK. The propriety or aptitude of expressing the time by the portions of the axis acg, will, perhaps,

appear more clearly in the following manner.

Let acg be any straight line, and let hk v be another line, straight or curved. Let the straight line ab z, perpendicular to ag, be carried uniformly down along this line, keeping always perpendicular to it, and therefore always parallel to its first position a h z. In its various fituations ckz, emz, &c. it will cut off areas ackh, aemh, &c. bounded by the axis by the ordinates ab and ck, or by the ordinates ab and em, &c. and by the line hkg. By this motion the moveable ordinate is faid, in the language of modern geometry, to generate the areas ackh, aemh, &c. At the fame time, let a point A move along the line ACG, fetting out from A at the instant when the line az fets out from a; and let the motion of the point A be fo regulated, that the spaces AB, AC, AD, &c. generated by this motion, may increase at the same rate with the areas a b, i h, a c k h, a d l h, &c. or fuch that we shall have AB to AC as abih to ackh, &c. It is plain, that the motion along AG is the same with that described in the enunciation of the proposition: for because the motion of the ordinate az, along the axis ag, is supposed to be uniform, the spaces a b, a c, a d, &c. are proportional to the times in which they are described, and may therefore be taken to measure or to represent thoie times.

Cor. 1. In a motion continually varied, the velocities in the different points of the path are to each other in the limiting or ultimate ratio of the spaces described in equal times, those times being supposed to diminish continually: for it is evident, that if the equal moments be, ed, ef, fg, are supposed to diminish continually, till the instants b and d coalesce with c, and the instants e and g coalesce with f; then the ratio of ck to fn is

the limit of the continually increasing ratio of op to fs, of A or of the continually diminishing ratio of cq to fr. Sir rater Isaac Newton calls this the ultimate ratio of cp to fs, Ret or of cq to fr. Now the ratio of cp to fs is, by construction, the same with the ratio of the rectangle btpc to the rectangle $f \circ x g$, and the ratio of aq to fr is the fame with the ratio of the rectangle cq vd to the rectangle eurf. But the ratio of the rectangle btpc to the restangle fs x g is the same with the ratio of the space bike to the space fnog; that is (by hypothesis), the same with the ratio of the space BC to the space FG; and the ratio of the rectangles cqvd and eurf is the same with that of the spaces CD and EF. Therefore the ratio of the velocity at C to the velocity at F is the fame with the ultimate ratio of the small increments BC, FG, or CD, EF of the spaces generated in very small and equal times.

It is also evident, that because the ratio of ck to fn is the limit both of the ratio of cp to fs and of the ratio of cq to fr, these ultimate ratios are the same, and that we may fay that the velocity in C is to the velocity in F in the ultimate ratio of BC to EF, or in the

ultimate ratio of CD to FG.

We also can easily perceive, that the ratio of the area bike to the area emnf approaches more near to the ratio of ck to fn as we take the moments bc and ef smaller. Therefore, in many cases of practice, where it may be easy to measure the spaces described in the different small moments of the motion, but difficult to ascertain their ultimate ratio, so as to obtain accurate measures of the proportions of the velocities, we may reduce the errors of measurement to something very infignificant, by taking these moments extremely small; and we shall diminish the error still more, by taking the proportion of the half fum of BC and CD to the half fum of EF and FG for the proportion of the velocities in C and F.

It often happens that we have it not in our power to compare the spaces described in small moments which are precisely equal. Still we can find the exact proportion of the velocities, if we can ascertain the ultimate ratio of the increments of the spaces, and the ultimate ratio of the moments of time in which these increments are defcribed: for it is plain, by confidering the gradual approach of the points p and r to the points k and n, that the ratio of c k to f n is still the ultimate ratio of the bases of rectangles equal to the mixtilineal areas, whether the altitudes (reprefenting the moments) are equal or not. Now the bases of two rectangles are in the proportion of the rectangles directly, and of their altitudes inverfely. But the ultimate ratio of the altitudes is the ultimate ratio of the moments, and the ultimate ratio of the rectangles is the ultimate ratio of the spaces described in those unequal moments. Therefore, in fuch cases, we have,

Cor. 2. The velocities are in the ratio compounded of ' 74. the direct ultimate ratio of the momentary increments of the spaces, and the inverse ultimate ratio of the increments (or moments) of the times in which these increments of the spa-

ces are made.

If s, v, and t, are taken to represent the magnitudes of the spaces, velocities, and times, and if s, v, and t, are taken always in the limiting or ultimate ratio of their momentary increments, we shall have v always in

ele-the proportion of s directly, and of s inversely. We ded express this by the proportional equation $v = \frac{s}{t}$, which

is equivalent to the analogy $V: v = \frac{\dot{S}}{\dot{T}}: \frac{\dot{s}}{\dot{r}}$, or V: v

= St:sT.

N. B. Here observe, that this is not the only way of flating the relation of space and time-the abscissa may be made the time and the ordinate the space; then the

velocity $=\frac{y}{x}$

The converse of this proposition may be thus ex-

pressed.

If the axis a g of the line h ko represent the time of a varied motion along the line AG, and if the ordinates a h, bi, ck, &c. be as the velocities in the inflants a, b, c, or in the points A, B, C; then the areas abih, ackh, adlh, &c. are proportional to the spaces AB, AC, AD,

This may be demonstrated in the same way with the former; but the indirect demonstration is more brief,

and equally strict.

If the spaces AC, AF, &c. are not proportional to the areas ackh, afnh, &c. they are proportional to fome other areas a c k h', a f n' h', &c. which are bounded by the same ordinates, and by another line b' k n'. But because the areas ackb, afn b, &c. are always proportional to the spaces AC, AF, &c. described on the line AG, the velocity in the point C is to the velocity in the point F as the ordinate ck is to the ordinate fn'. But, by hypothesis, the velocity in C is to the velocity in F as ck to fn, and fn' is equal to fn; which is absurd. Therefore the spaces AC, AF, are not proportional to any other areas, &c.

Cor. The ultimate ratio of the momentary increments of the spaces is compounded of the ratio of the velocities, and the ultimate ratio of the increments of the times: for when the moments bc, ef, are equal, it is evident, that the ultimate ratio of the rectangles bept, efru is the same with the ultimate ratio of the increments of the spaces. But the ultimate ratio of these rectangles is the same with that of their bases cp and fr; that is, the ratio of ck to fn, that is, the ratio of the velocities. And when the moments are unequal, the ratio of the rectangles is compounded of the ratio of their bases and the ratio of their altitudes; that is, compounded of the ratio of the velocities and the ultimate ratio of the moments of time.

We have, therefore, S:s = VT: vt, and s = vt. It most commonly happens, that we can only observe the accumulated refults of varied motions; and in them we only observe a space passed over, and a certain portion of time that has elapfed during the motion. But being able to distinguish the portions of the whole space which are described in known portions of the whole time, and having made fuch observations in several parts of the motion, we discover the general law that the motion affects, and we affirm this law to hold univerfally, even though we have not observed it in every point. We do this with a degree of probability and confidence proportioned to the frequency of our observation. It is not till we have done this, that we can make use of

the first of these two propositions, which enables us to Of Acceles ascertain the velocity of the motion in its different moments. Thus if we observe, that a stone in falling de- Motions. feends one foot in the quarter of a fecond, 16 feet in a second, 64 feet in two feconds, and 144 feet in three seconds; the general law immediately observed is, "that the spaces described are as the squares of the times;" for 1 is to 16 as the square of $\frac{1}{4}$ to the square of 1. Again, 16 is to 64 as 12 to 22; and 16 is to 144 as 12 to 32. Hence we infer, with great probability, that the stone would fall 36 feet in a second and a half; for 16 is to 36 as 12 to 112; and we conclude in the same way for all other parts of the motion.

This immediate observation of the analogy between A good exthe spaces and the squares of the times suggests an easy ample of determination of the velocity in this particular kind of the geomemotion; and it merits particular notice, being very often thod. referred to. We can take ag to represent the time; and then, because the areas which are to represent the spaces described must be proportioned to the squares of the portions of a g, we perceive that the line which comes in place of h k o must be a straight line drawn from a. For example, the straight line asy. For this is the only boundary which will give areas a b \beta, ac x, a d \delta, &c. proportional to a b2, a c2, a d2, &c. And we perceive, that any straight line drawn from a will have this pro-

Having thus got our representations of the times and the spaces, we say, on the authority of our theorem. that the velocity at the instant b is to the velocity at the instant d as $b\beta$ to $d\delta$, &c. And now we begin to make inferences, purely geometrical, and express our discovery of the velocities in a very general and simple manner. We remark, that b \beta is to d \s as a b is to a d; and we make the same affirmation concerning the magnitudes represented by these lines. We say that the velocity at the instant b is to the velocity at the instant d as the time a b is to the time a d. We fay, in terms still more general, that the velocities are proportional to the times from the beginning of the motion. We moreover perceive, that the spaces are also proportional to the squares of the acquired velocities; or the velocities are as the square roots of the spaces.

We can farther infer, from the properties of the triangle, that the momentary increments of the spaces are proportional to the momentary increments of the squares of the times, or of the squares of the velocities.

We also observe, that not only the whole acquired velocities are proportional to the whole elapfed times, but that the increments of the velocities are proportional to the times in which they are acquired; for # x is to $\rho \varphi$ as b c to df, &c. Equal increments of velocity are therefore acquired in equal times. Therefore fuch a motion may, in great propriety of language, be denominated a Uniformly Accelerated motion; that is, a motion in which we observe the spaces proportioned to the squares of the times, is a motion uniformly accelerated; and spaces in the duplicate ratio of the times form the oftenfible characteristic of an uniformly accelerated motion.

Laftly, if we draw "> parallel to the axis a b, we perceive that the rectangle ae : x is double of the triangle a e . Now because a e represents the time of the motion, and e represents the acquired velocity, the rectangle a e e x will represent the space which would be uniformly described with the velocity e during the time

Of Accele- ae. But the triangle ae represents the space really rating and described with the uniformly accelerated motion during Retarding the fame time. Hence we infer, that the space that is - described in any time, with a motion increasing uniformly from nothing, is one half of the space which would be uniformly described during the same time with the final velocity.

> These are but a part of the inferences which we may draw from the geometrical properties of those representations which we had selected of the different measureable affections of motion. We may affirm, with respect to the motions themselves, all the inferences which relate to magnitude and proportion, and thus improve our

knowledge of the motions.

We took the opportunity of this very fimple and perspicuous example, to give our young readers a just conception of the mathematical method of profecuting mechanical knowledge, and to make them fenfible of the unquestionable authority for every theorem deduced in this manner.

One of the most important is, to discover the accumulated refult of a motion of which we only observe the momentary increments. This is to be done by finding the area, or portions of the area, of the mixtilineal space a g's h; and it is evidently analogous to the inverse method of fluxions, or the integral calculus.

In most cases, we must avail ourselves of the corollary s = vt, and we obtain the folution of our question only in the cases where our knowledge of the quantities s, t, and v (confidered as geometrical magnitudes, that is, as lines and furfaces), enables us to discover

s and t.

OF ACCELERATING AND RETARDING FORCES.

HAVING thus discovered the proportions of the velocities in motions varying in any manner whatever, we can observe the variations which happen in them. These variations are the effects, and the only marks and meafures, of the changing forces. They are the characteriftics of their kinds (confidered merely as moving forces); that is, the indications of the directions in which they act; for this is the only difference in kind of which they are susceptible in this general point of view. If they increase the velocity, their direction must be conceived as the same with that of the previous motion; because the result of the action of a force is equivalent to the composition of the motion which that force would produce in a quiescent body with the motion already exilting; and an increase of velocity is equivalent to the composition of a motion in the same direction.

Having no other mark of the force but the acceleration, we have no other name for it in the abstract doctrines of dynamics, and we call it an ACCELERATING FORCE. Had it retarded the motion, we should have

called it a RETARDING FORCE.

In like manner, we have no measure of the magnitude or intensity of an accelerating force, but the acceleration which it produces. In order therefore to investigate the powers which produce all the changes of motion, we must endeavour to obtain measures of the accelera-

A continual increase of velocity is the effect of the continued action of accelerating forces. If equal increments of velocity are produced in every fucceeding equal moment of time, we cannot conceive that there is

any change in the accelerating force. Therefore a uni Of formly accelerated motion is the mark of the unvaried pat action of an accelerating force, that is, of the continued Ret action of a constant force; of a force whose intensity is always the same. When therefore we observe a body describe spaces proportional to the squares of the times, we must infer that it is urged forward by a force whose intenfity does not change; and, on the other hand, a constant force must produce a uniformly accelerated mo. tion by its continued action. And if any previous circumflances affure us of this continued action of an invaried force, we may make all the inferences which were mentioned under the article of uniformly accelerated motion.

That force must furely be accounted double which Mea produces a double increment of velocity in the same anal time by its uniform action, we can form no other efficing mation of its magnitude. And, in general, accelerating forces must be accounted proportional to the increments of velocity which they produce, by ading uniformly during

the same or equal times.

Supposing them to act on a body at rest. Then the velocity produced is itself the increment; and we must fay, that accelerating forces are proportional to the velocities which they generate in a body in equal times. And because we found (no 79.), that the space described with a uniformly accelerated motion is half the space which would be uniformly described in the same time with the final velocity, which space is the direct measure of this velocity, and because halves have the fame proportion with the wholes-we may fay, that accelerating forces are proportional to the spaces through Amount they impel a body from rest in equal times by their mea

uniform action.

This is an important remark; because it gives us an easy measure of the force, without the trouble of first computing the velocities. It also gives us the only diftine notion that we have of the measurement of forces by the motions which they produce. When speaking of the composition of forces, we distinguished or denominated them by the fides and diagonal of a parallelogram. These lines must be conceived as proportional to the spaces through which the forces urge the body uniformly during the small and insensible time of their action, which time is supposed to be the same for both forces; for the fides of the parallelogram are supposed to be separately described in equal times, and therefore to be proportional to the velocities generated by the constituent forces. If indeed the forces do not ast uniformly, nor fimilarly, nor during equal times, we cannot fay (without farther investigation) what is the proportion of the intenlity of the forces, nor can we infer the composition of their action. We must at least suppose, that in every instant of this very small time of their joint action, their direction remains unchanged, and that their intensities are in the same ratio. We shall see by and bye, that with these conditions the sides of the parallelogram are still proportional to the velocities generated. In the mean time, we may take the spaces through which a body is uniformly impelled from rest (that is, with a uniformly accelerated motion) as the measures of the forces; yet these spaces are but the halves of the measures of the velocities. I hen, if a body be moving with the velocity of 32 feet per second, and an accelerating force acts on it during a fecond,

cele- and if this force be such that it would impel the body and (from a state of rest) 16 feet, it will add to the body a ding velocity of 32 feet per fecond. Accordingly, this is the effect of gravity—the weight of a pound of lead may be confidered as a force which does not vary in its intenfity. We know that it will cause the lead to fall 16 feet in a second; but if the body has already fallen 16 feet, we know that it is then moving with the velocity of 32 feet per second. And the fact is, that it will fall 48 feet farther in the next fecond, and will have acquired the velocity of 64 feet per fecond. It has therefore received an augmentation of 32 feet of velocity by the action of gravity during the fecond fecond; and gravity is in fact a constant force, causing equal increments of velocity in equal times, however great the velocities may be. It does not act like a stream of sluid, whose impulse or action diminishes as the solid body withdraws from it by yielding.

But supposing that we have not compared the increments of velocity uniformly acquired during equal times, in what manner shall we measure the accelerating forces? In fuch a case, that force must be accounted double which generates the same velocity, by acting uniformly during half the time; for when the force is fupposed invariable, the changes of velocity which it produces are proportional to the times of its action; therefore if it produces an equal velocity in half the time, it will produce a double velocity in an equal time, and is therefore a double force. The fame may be faid of every proportion of time in which an equal change of velocity is produced by the uniform action of an accelerating force. The force must be accounted greater in the same proportion that the time required for the production of a given velocity in a body is less. Hence we infer, that accelerating forces are inverfely proportional to the times in which a given change of velocity is produced by their uniform action.

By combining these two propositions we establish this general theorem;

re of Accelerating forces are proportional to the changes of velocity which they produce in a body by their uniform action directly, and to the times in which thefe changes are produced inverfely.

If, therefore, A and a are the forces, V' and v' the changes of velocity, and 'I' and t' the portions of time

in which they are uniformly produced, we have
$$A: a = V't': v'T', = \frac{V'}{T'}: \frac{v'}{t'}$$
 And $a = \frac{v'}{t'}$

The formula $a = \frac{v'}{t'}$ is not reftricted to any particular magnitude of v' and t'. It is true, therefore, when the portion of time is diminished without end; for fince the action is supposed uniform, the increment of velocity is lessened in the same proportion, and the

value of the fraction "remains the fame. The characters or fymbols w and t are commonly used to express finite portions of v and t. The symbols v and t are used by Newton to express the same things taken in the ultimate or limiting ratio. They are utually confidered as indefinitely small portions of v and t. We shall

abide by the formula $a = \frac{v}{1}$.

SUPPL. VOL. I. Part II.

It must always be kept in mind, that v and t are ab- Of Accele-It must always be kept in initia, that v unit of space, rating and fract numbers; and that v refers to some unit of space, Retaiding fuch as a foot, an inch, a yard; and that t refers to fome unit of time, fuch as an hour, a minute, a fecond; and especially that a is the number of the same units and especially that a is the number of the fame unit is an about space, which will be uniformly described in one unit is an about that fame thrust numof the time with the velocity generated, by the force ber. acting uniformly during that unit. It is twice the fpace actually described by the body during that unit when impelled from rest by the accelerating force. It is necessary to keep hold of these clear ideas of the quantities expressed by the symbols.

On the other hand, when the measure of the accelera-Measure of ting force is previously known, we employ the theorem a change of at' = v'; that is, the addition made to the velocity velocity. during the whole, or any part, of the time of the action of the force is obtained by multiplying the acceleration of one unit of time by the number of fuch units con-

tained in t'. These are evidently leading theorems in dynamics; These meabecause all the mechanical powers of nature come unfures ex-der the predicament of accelerating or retarding forces. grearest It is the collection of these in any subject, and the man-part of our ner in which they accompany, or are inherent in it, knowledge which determine the mechanical character of that fub of mechaiect: and therefore the phenomena by which they are nical naject; and therefore the phenomena by which they are ture. brought into view are the characteristic phenomena. Nay, it may even be questioned, whether the phenomena bring any thing more into view. This force, of which we speak so samiliarly, is no object of distinct contem. plation; it is merely a fomething that is proportional

to $\frac{v}{t}$. And when we observe, that the $\frac{V}{rt}$, found in the motions that refult from the vicinity of a body A, is double of the $\frac{v}{\cdot}$, which refults from the vecinity of

another body B; we fay that a force refides in A, and that it is double of the force refiding in B. The accelerations are the things immediately and truly expressed by these symbols. And the whole science of dynamics may be completely taught without once employing the word force, or the conception which we imagine that we form of it. It is of no use till we come to study the mechanical history of bodies Then, indeed, we must have some way of expressing the fact, that an acceleration $=\frac{32 \text{ feet}}{1''}$ is observed in every thing on

the furface of this globe; and that an acceleration = 418 feet is observed over all the surface of the sun. These facts are characteristic of this earth and of the sun; and we express them shortly by faying, that such and such forces refide in the earth and in the fun. It will preferve us from many mistakes and puzzling doubts, if we resolutely adhere to this meaning of the term force; and this will carry mathematical evidence through the

whole of our investigations. As velocity is not an immediate object of contem-Another plation, and all that we observe of motion is a space measure of and a time, it may be proper to give an expression of accelera this measure of accelerating force which involves no ting force. other idea. Suppofing the body to have been previ-

outly at reft, we have $a = \frac{\pi}{x}$. Multiply both parts

530

Of Accele of the fraction by t, which does not change it value, rating and Retarding and we have $a = \frac{vt}{t^2}$. But vt = s; and therefore a

The formula $a = \frac{s}{t^2}$ is equivalent to the proportion

 $t^2: 1 = s: a$; and a would then be the space through which the accelerating force would impel the body in one unite of the time t. But this is only half of the measure of the velocity which the accelerating force generates during that unit of time. For this reason we did not express the accelerating force by an ordinary equation, but used the symbol =. In this case, therefore, of uniform action, we may express the accelera-

ting force by $a = \frac{2s}{t^2}$.

The following theorem is of still more extensive use in all dynamical disquisitions.

ting force.

Most gene-Accelerating forces are proportional to the momentary increments of the squares of the velocities directly, and as the spaces along which they are uniformly acquired in-

> Let A'B, A'C, and AD (fig. 14.), be three lines, described in the same or equal times by the uniform action of accelerating forces; the motions along these lines will be uniformly accelerated, and the lines themfelves will be proportional to the forces, and may be employed as their measures. On the greatest of them AD, describe the semicircle ABCD, and apply the other two lines A'B, A'C as chords AB, AC. Draw EB, FC perpendicular to AD. Take any fmall portions B b, C c of AB and AC, and draw b c, cf perpendicular to AD, and Eh and Fk parallel to AB and AC.

> Then, because the triangles DAB and BAE are frmilar, we have AD: AE = AD2: AB2. And because AD is to AB as the velocity generated at D is to the velocity generated at B (the times being equal), we have AD to AE as the square of the velocity at D to the square of the velocity at B; which we may express thus:

 $AD : AE = V^2, D : V^2, B.$

For the fame reasons we have also

 $AD : AF = V^2, D : V^2, C.$ Therefore

 $AE : AF = V^2$, $B : V^2$, C.

But because in any uniformly accelerated motion, the spaces are as the squares of the acquired velocities, we have also

 $AE : Ae = V^2$, $B : V^2b$, and $AF : Af = V^2, C : V^2 c.$

Therefore E_e is to F_f as the increment of the square of the velocity acquired in the motion along B b to the increment of the square of the velocity acquired along

But, by fimilarity of the triangles ABD and E e h, we have

AB : AD = Ee : Eh; and, in like manner,

AD : AC = Fk : Ff. Therefore $AB : AC = Ee \times Fk : Ff \times Eb$.

Now AB and AC are proportional to the forces which accelerate the body along the lines A'B and A'C; E e and F f are proportional to the increments of the squares of the velocities acquired in the motions

along the portions B b and C c; and E b and F l are Of Acc equal to those portions respectively. The ratio of AB rating to AC is compounded of the direct ratio of E e to F f; Retaid Force and F f to F l. The proposition and the inverse ratio of E h to F k. The proposition is therefore demonstrated.

The proportion may be expressed thus:

AB: AC = $\frac{E e}{E h}$: $\frac{F f}{F k}$, and may be expressed by

the proportional equation $AB \stackrel{\cdot}{=} \frac{E e}{E h}$ or, fymbolical-

ly, $a = \frac{(v^2)}{\cdot}$

REMARK. Because the motion along any of these visb three lines is uniformly accelerated, the relation between one-hal spaces, times, and velocities, may be represented by of the means of the triangle ABC (fig. 15.); where AB recement presents the time, BC the velocity, and ABC the space. If BC be taken equal to AB, the triangle is half of the square ABCF of the velocity BC; and the triangle ADE is half of the square ADEG of the velocity DE. Let D d and B b be two moments of time, equal or unequal. Then D de E and B b c C are half the increments of the squares of the velocities DE and BC, acquired during the moments Dd and Bb. It was demonstrated, that the ratio of the area D de E to the area BbcC is compounded of the ratio of DE to BC, and the ultimate ratio of Dd to Bb. But Dd and B b are respectively equal to ee and x c. Therefore D de E is to B b c C, in the ratio compounded of the ratio of DE to BC, and the ultimate ratio of ee to x c. If we represent DE and BC by V and v, then ie and * c must be represented by V' and v', the increments of V and v; and then the compound ratio will be the ratio of VV' to vv'; and if we take the ultimate ratio of the moments, and consequently the ultimate ratio of the increments of the velocities, we have the ratio of VV to v v. If, therefore, V2 and v2 represent the squares of the velocities, VV and v will represent, not the increments of those squares, but half the increments of them.

We may now represent this proposition concerning accelerating forces by the proportional equation a =

 $\frac{vv}{}$; and we must consider this as equivalent with a =

 $\frac{V^2-v^2}{2(S-s)}$; keeping always in mind, that a, V, and v, relate to the same units of time and space, and that a is that number of units of the scale on which S and s are measured, which is run over in one unit of time.

This will be more clearly conceived by taking an Meafer example. Let us afcertain the accelerative power of gravit gravity, supposing it to act uniformly on a body. Let confid the spaces be measured in feet and the time in seconds. legating It is a matter of observation, that when a body has fal-sorce. len 64 feet, it has acquired a velocity of 64 feet per fecond: and that when it has fallen 144 feet, it has acquired the velocity of 96 feet per fecond. We want to determine what velocity gravity communicated to it by acting on it during one fecond. We have V' = 9216, and $v^2 = 4096$; and therefore $V^2 - v^2 = 5120$. S = 144, and s = 64, and S - s = 80, and 2(S - s)

= 160. Now $a = \frac{5120}{160}$, = 32. Therefore gravi-

g ccele ty has generated the velocity 32 feet per second by y and acting uniformly during one second.

The augmentation of the square of the velocity is preportional to the force and to the space jointly. For, because

$$a = \frac{vv}{\cdot}$$
, we have $as = vv$.

orems

eting

ding

Thus we learn, that a given force, acting uniformly on a body along a given space, produces the same increment of the square of the velocity, whatever the previous velocity may have been. Also, in the same man. ner as we formerly found that the augmentation of the velocity was proportioned to the time during which the force has acted, fo the augmentation of the square of the velocity is proportional to the space along which it

It is pretty plain, that all that we have faid of the uniform action of an accelerating force may be affirmed of a retarding force, taking a diminution or decrement of velocity in place of an increment. A uniformly retarded motion is that in which the decrements of velocity in equal times are equal, and the whole decrements are proportional to the whole times of action. Such a motion is the indication of a constant or invariable force acting in a direction opposite to that of the motion. We conceive this to be the case when an arrow is shot perpendicularly upwards; its weight is conceived as a force continually preffing it perpendicularly downwards.

In fuch motions, however great the initial velocity may be, the body will come to rest; because a certain determined velocity will be taken from the body in each equal successive moment, and some multiple of this will exceed the initial velocity. Therefore the velocity will be extinguished before the end of a time that is the same multiple of the time in which the velocity was diminished by the quantity above mentioned. It is no less evident, that the time in which any velocity will be extinguished by an opposing or retarding force is equal to the time in which the same force would generate this velocity in the body previoufly at rest. Therefore,

1. The times in which different initial velocities will be extinguished by the same opposing force are propor-

tional to the initial velocities.

2. The distances to which the body will go till the extinction of its velocity are as the squares of the initial

3. They are also as the squares of the times elapsed.

4. The distance to which a body, projected with any velocity, will go till its motion be extinguished by the uniform action of a retarding force, is one half of the space which it would describe uniformly during the fame time with the initial velocity.

IT very rarely happens, that the force which acceleally va- rates the body acts uniformly, or with an unvaried in-le in tensity. The attraction of a magnet, for example, in-ir inten-creases as the iron approaches it. The pressure of a spring diminishes as it unbends. The impulse of a stream of water or wind diminishes as the impelled surface retires from it by yielding. Therefore the effects of accelerating forces are very imperfectly explained, till we have shewn what motions result from any given variation of force, and how to discover the variation of force from the observed motion. This last question is per-

haps the most important in the study of mechanical na- Of Acceleture. It is only thus that we learn what is usually call-Retarding ed the nature of a mechanical force. This chiefly con-Forces. fifts in the relation subfifting between the intensity of . the force and the distance of the substance in which it refides. Thus the nature of that power which produces all the planetary motions, is confidered as afcertained when we have demonstrated that its pressure or intenfity is inversely as the square of the distance from the body in which it is supposed to reside.

Acceleration expresses some relation of the velocity and time. This relation may be geometrically expreffed in a variety of ways. In figure 13. the uniform acceleration or the unvaried relation between the velocity and the time is very aptly expressed by the constant ratio of the ordinates and abscisses of the triangle ag_{γ} . The ratio of $d \delta$ to a d is the fame with that of e: to ae, or that of f o to af, &c.; or the ratio of the increment of velocity = * to the increment of the time β w or bc, or that of i φ to ii, &c. This ratio wx:β w

is equivalent to the fymbol -

But when the spaces described in a varied motion are reprefented by the areas bounded by a curve line hko, we no longer have that constant ratio of the increments of the ordinates and abscisses.

Therefore, in order to obtain measures of the acce- Their meas lerating forces, or at least of their proportions, let the fures in furch cases abscissa aeg (fig. 13.) of the line h ko again repre-howobtainfent the time of a motion. But let the areas boundeded? Theoby parallel ordinates now reprefent the velocities, that rems of is, let the whole area increase during the time ag at five use. the fame rate with the velocities of the motion along the line AG. In this case the ordinates bi, ck, dl, &c. will be as the accelerations at the inflants b, c, d,

&c. or in the points B, C, D, &c.

This is demonstrated in the same way as the former proposition (n° 72.). If the accelerating force be supposed constant during any two equal moments bc and fg, the rectangles b c p t and $fg \times s$ would express the increments of velocity uniformly acquired in equal times, and their bases cp and fs would have the ratio of the accelerations, or of the accelerating forces. But as the velocities expressed by the figure increase faster than the times during every moment, the force at the instant c is to the force at the instant f in a greater ratio than that of cp to fs; but, for similar reasons, it is in a less ratio than that of cq to fr; and therefore (as in the other proposition) the force at the instant c is to the force at the instant f as ck to fn.

Cor. Because cp is to fs in the ratio compounded of the direct ratio of the rectangle cpt b to the rectangle $f s \times g$, and the inverse ratio of the altitude b c to the altitude $f_{\mathcal{S}}$; and because these rectangles are proportional to the increments of velocity, and the ultimate ratio of the altitudes is the ultimate ratio of the moments or increments of the time-we must say, that the accelerating forces (that is, their intensities or pressures producing acceleration) are directly as the increments of velocity, and inversely as the increments of the times: Which proposition may be expressed, in regard to two accelerations A and a, by this analogy:

$$A: a = \frac{\dot{V}}{\dot{T}}: \frac{\dot{v}}{\dot{t}}$$

Of Accele-Retaiding Forces.

rating and Or by the proportional equation $a = \frac{v}{\cdot}$. Also at

 $=\dot{v}$, and $\int at = v'$. And thus do thefe theorems extend even to the cases where there cannot be observed an immediate measure, either of velocity or of acceleration; because neither the space nor the velocity increases uniformly.

See Barrorv's Lea. Geometr paffim.

The theorem $a = \frac{v}{t}$ is employed when we would

discover the variation in the intensity of some natural power. We observe the motion, and represent it by a figure analogous to fig. 13. where the absciffa represents the times, and the area is made to increase at the same rate with the spaces described. Then the ordinates will represent the velocities, or have the proportion of the velocities. Then we may draw a fecond curve on the other fide of the same abscissa, such that the areas of this last curve shall be proportional to the ordinates of the first. The ordinates of this last curve

are proportional to the accelerating forces.

On the other hand, when we know from other circumstances that a force, varying according to some known law, acts on a body, we can determine its motion. The intenfity of the force in every instant being known, we can draw a line fo related to another line reprefenting the time that the ordinates shall be proportional to the forces: The areas will be proportional to the velocities. We can draw another curve to the fame absciss, such that the ordinates of this shall be proportional to the areas of the other, that is, to the velocities of the motion. The areas of this fecond curve will be proportional to the spaces described.

We must now observe, that all that has been faid concerning the effects of accelerating forces continually varying, relates to changes of motion, independent of what the absolute motions may be. The areas of the line whose ordinates represent the velocities do means they not necessarily represent the spaces described, but the indicate im-change made on the spaces described in the same time; mediately the notions but the changes of motion. If, inoperation of not the motions, but the changes of motion. If, indeed, the body be supposed to be at rest when the forces begin to act, these areas represent the very spaces that are passed over, and the ordinates are the very velocities. In every case, however, the accelerations are

the real increments of the velocities.

This circumstance gives a great extension to our theorems, and enables us to ascertain the disturbances of any species of regular motion, apart from the motions themselves, and thus avoid a complication which would frequently be inextricable in any other way. And this process, which is merely mathematical, is perfectly conformable to mechanical principles. It is in fact an application of the doctrine of the composition of motion; a doctrine rigidly demonstrated when we measure a mechanical force by the change of motion which it produces. Acceleration is the continual composition of a new motion with the motion already produced.

We may learn from this investigation of the value of change of velocity can be produced effected in an inftant by the action of an accelerating in an inftant force. When the fig. 13. is used for the scale of acceby any ac- lerations, and they are represented by the ordinates of celerating the line hko, the increment of velocity is represented

by an area, that is, by a flip of the whole area; which Of Ac flip must have some altitude, or must occupy some por-rating Retar tion of the abscissa which represents time. Some por-Force tion of time, however small it may be, must elapse be. . fore any measurable addition can be made to the velocity. The velocity must change continually. As no motion can be conceived as instantaneous, because this would be to conceive, that in one instant the moving particle is in every point of its momentary path; fo no velocity can change, by a finite quantity, in one instant; because this would be to conceive, that in that instant the particle had all the intervening velocities. The instant of change is at once the last instant of the preceding velocity, and the first of the succeeding, and therefore must belong to both. This cannot be conceived, or is absurd. As a body, in passing from one part of space to another, must pass in succession through all the intermediate places; fo, in passing from one velocity to another, it must in succession have all the intermediate velocities. It must be continually accelerated; we must not say gradually, however small the

But to return from this digression:

The most frequent cases which come under examina- More tion do not shew us the relation between the forces and venient times, but the relation between the forces and spaces. consider the state of the consideration of the considerati Thus, when a piece of iron is in the neighbourhood of the act a magnet, or a planet is confidered in the neighbour-of force hood of the fun, a force is acting on it in every point and me of its path, and we have discovered that the intensity frequen of its path, and we have discovered that the intensity coming of this force varies in a certain proportion. Thus, ato view fpring varies in its pressure as it unbends; gunpowder presses less violently as it expands, &c. &c.

Our knowledge is generally confined to some such effect as this. We know, that while a body is moving along a line ADE (fig. 16.), it is urged forward by a force, of which the intensity varies in the proportion of the ordinates BF, CG, DH, EI, &c. of the line

FGHI.

To investigate the motion or change of motion produced by the action of this force, let CD be supposed a very finall portion of the space s, which we may express by s'. Draw GK perpendicular to DH. Then, if we suppose that the force acts with the unvaried intensity CG through the whole space CD, the rectangle CDKG will express half of the increment of the square of the velocity (no 85.). We may suppose that the force acts uniformly along the adjoining small space Dr with the intensity DH. The rectangle DH or will in like manner express another half increment of the square of the velocity. And in like manner we may obtain a succession of such increments. The aggregate or fum of them all will be half the difference between the square of the velocity at B and the square of the velocity at E.

If we employ f to express the indetermined or variable intensity of the accelerating force, and v to express the variable velocity, and v' its increment uniformly acquired; then the rectangle CDKG will be expressed by fs'. We have seen that this is equal to vv'. Therefore, in every case where we can tell the aggregate of all the quantities fs, it is plain that we will obtain half the difference between the squares of the velocities in B and E, on the supposition that the intensity of the force was conftant along each little space, and

92

All these theorems relate to

powers.

25 1. t im-

; ant

rem

cheele- varied by starts. Then, by increasing the number, and and diminishing the magnitude, of those little portions of arding the space without end, it is evident that we terminate in the expression of the real state of the case, i.e. of a force varying continually; and that in this case the aggregate of these rectangles occupies the whole area AEIF, and is equivalent to the fluent of fs, or to the symbol //s, used by the foreign mathematicians to express this fluent, which they indeed conceive as an aggregate of small rectangles fs'. And we see that this area expresses half of the augmentation of the square of

the velocity. Therefore,

If the abscissa AE (fig. 16.) of a line FGI is the path along which a body is urged by any accelerating force, and if the ordinates BF, CG, DH, &c. are proportional to the forces acting in the points B, C, D, &c. the intercepted areas BCGF, BEIF, &c. are proportional to the

augmentations of the square of the velocity.

Observe that the areas BCGF and DEIH are also proportional to the augmentations made on the squares

of the velocities in B and in D.

Observe also, that it is indifferent what may have been the original velocity. The action of the forces represented by the ordinates make always the same addition to its square; and this addition is half the square of the velocity which those forces would generate in the body by impelling it from rest in the point A.

Lastly, on this head, observe, that we can state what constant or variable force will make the same augmentation of the square of the velocity by impelling the body uniformly along the same space BE; or along what space a given force must impel the body, in order to produce the same increase of the square of its velocity. In the first case, we have only to make a rectangle BEN, equal to the area BEIF, and then B, is the intensity of the constant force wanted. In the second case, in which the force EO is given, we must make the rectangle A a OE equal to the area BEIF, and AE is the space required.

or The converte of this proposition, the orverse. are as the increments of the fquare of the velocity, the or-The converse of this proposition, viz. If the areas dinates are, as the forces, is eafily demonstrated in the same way; for if the elementary areas CDKG and EIM e represent increments of the squares of the velocity, the accelerating forces are in the ratio compound, ed of the direct ratio of these rectangles and the inveise ratio of their altitudes, because these altitudes are the increments of the space (nº 85.) Now the base CG of the rectangle CDKG, is to the base EI of the rectangle EIM e in the same compounded ratio; there. fore the force in C is to the force in E as CG to EI.

The line hko (fig. 13.) was called by Dr Barrow (who first introduced this extensive employment of moy, act tion into geometry), the SCALE of velocities; and the line ration, FHL (fig. 16.) was named by him the scale of accelerations. Hermann, in his Phoronomia, calls it the scale of forces. We shall retain this name, and we may call bko of fig. 13. the fcale of accelerations, when the areas reprefent the velocities. Sir Ifaac Newton added another scale of very great use, viz. a scale of times. It is constructed as follows.

Let ABE (fig. 16.) be the line along which a body is accelerated, and let FHI be the scale of forces, that is, having its ordinates FB, HD, IE, &c. proportional to the forces acting at B, D, E, F, &c.; let fhi be arch Hh=fF, and draw hc parallel to HC; join

another line so related to ABE, that Cg is to Ei in Of Accelethe inverse subduplicate ratio of the area BFGC to rating and the area BFIE; or, to express it more generally, let Retarding Forces. the squares of the ordinates to the line fg i be inversely, as the areas of the line FHI intercepted between these ordinates and the first ordinat drawn through B; then the times of the bodies moving from a flate of rest in B are as the intercepted areas of the curve fg i.

For let CD and E e be two very small portions of the space described in equal times. They will be ultimately as the velocities in C and E. The area FBCG is to the area FBEI as the square of E i to the square. of Cg (by construction); but the area FBCG is to FBEI as the square of the velocity at C to the square of the velocity at E (by the proposition); therefore the square of the velocity at C is to the square of the velocity at E as the square of Ei to the square of Cg; therefore Ei is to Cg as the velocity at C to the velocity at E, that is, as CD to to E_e : but fince E_i : $C_g = CD$: E_e , we have E_i \times E $e = C g \times C D$, and the elementary rectangles CgkD and Eime are equal, and may represent the equal moments of time in which CD and Ee were described. Thus the areas of the line fg l will represent or exprefs the times of describing the corresponding portions of the abscissa.

We may express the nature of this scale more briefly thus. Let BE be the space described with any varied motion, and fg l a curve, such that its ordinates are inversely as the velocities in the different points of the abscissa, then the area will be as the times of describing

the corresponding portions of the abscissa.

In all the cases where our mathematical knowledge Examples enables us to affign the values of the ordinates of the fi- of the apgure 16, we can obtain the law of action of the forces, plication of or the nature of the force; and where we can affign no 95. the value of the areas from our knowledge of the proportions of the ordinates or forces, we can afcertain the velocities of the motion. We shall give an example or two, which will shew the way in which we avail ourselves of the geometrical properties of figure in order to ascertain the effects of mechanical forces.

1. Let the accelerating force which impels the body along the line AB be constant, and let the body be previously at rest in B; the line which bounds the ordinates that represent the forces must be some line HN parallel to AB. The area BDH p is to the area BEN p as the square of the velocity at D to the square of the velocity at E. These areas, having equal bases DH and EN, are as their altitudes BD and BE. That is, the spaces described are as the squares of the acquired velocities. And we see that this characteristic mark of uniformly accelerated motion is included in this

general proposition. 2. Let us suppose that the body is impelled from A Example (fig. 17.) towards the point C; by a force proportional fecond of to its distance from that point. This force may be re- eculiar presented by the ordinates DA, EB, eb, &c. to the ance.

straight line DC. We may take any magnitude of these ordinates; that is, the line DC may make any angle with AC. It will simplify the investigation if we make the first force AD = AC. About C describe the circle AH a, cutting the ordinate EB in F; let eb be another ordinate, cutting the circle in f very near to F; draw CH perpendicular to AC, and make the

Forces.

Of Accele: FC and DH, and draw Fg perpendicular to fb. Let rating and IML be another ordinate.

The area DABE is to the area DAKL as the I fquare of the velocity at B to the square of the velocity at K. But DABE is the excess of the triangle ADC above the triangle EBC, or it is half of the excess of the square of CA or CF above the square of CB, that is, half the square of BF. In like manuer, the area DAKL is equal to half the square of KM; but halves have the fame ratio as the integers; therefore the square of BF is to the square of KM as the , square of the velocity at B to the square of the velocity at K; therefore the velocity at B is to the velocity at K as BF is to KM. The velocities are proportional to the fines of the arches of the quadrant AFH described on AC.

Cor. 1. The final velocity with which the body arrives at C, is to the velocity in any other point B as

radius to the fine of the arch AF.

Cor. 2. The final velocity is to the velocity which the body would acquire by the uniform action of the initial force at A as 1 to 12; for the rectangle DA CH expresses the square of the velocity acquired by the uniform action of the force DA; and this is double of the triangle DAC; therefore the squares of these velocities are as I and 2, and the velocities are as VI and $\sqrt{2}$, or as I to $\sqrt{2}$.

Cor. 3. The time of describing AB is to the time of describing AC as the arch AF to the quadrant

For when the arch F f is diminished continually, it is plain that the triangle fi F is ultimately fimilar to CFB, by reason of the equal angles Cib (or CFB) and fi F, and the right angles CBF and f F i; therefore the triangles fg F and CBF are also fimilar. Moreover, B b is equal to Fg, F f is equal to b H, which is ultimately equal to c C; therefore fince the triangles fg F and CFB are similar, we have F g: F f = FB: FC, = FB: HC; therefore B b is to c C as FB to HC, that is, as the velocity at B to the velocity at C; therefore B b and c C are described in equal moments when indefinitely fmall; therefore equal portions Ff, hH, of the quadrant correspond to equal moments of the accelerated motion along the radius AC; and the arches AF, FM, MH, &c. are proportional to the times of describing AB, BK, KC. &c.

Cor. 4. The time of describing AC with the unequally accelerated motion, is to the time of describing it uniformly with the final velocity as the quadrantal arch is to the radius of a circle; for if a point move in the quadrantal arch so as to be in F, f, M, H, &c. when the body is in B, b, K, C, it will be moving uniformly, because the arches are proportional to the times of describing those portions of AC; and it will be moving with the velocity with which the body arrives at C, because the arch h H is ultimately = Cc. Now if two bodies move uniformly with this velocity, one in the arch AFH, and the other in the radius AC, the times will be proportional to the spaces uniformly defcribed; but the time of describing AFH is equal to the time of the accelerated motion along AC; therefore the proposition is manifest.

Cor. 5. If the body proceed in the line Ca, and be retarded in the fame manner that it was accelerated along AC, the time of describing AC uniformly with

the velocity which it acquires in C is to the time of Of Acc describing AC a with the varied motion, as the diame- rating ter of a circle to the circumference; for because the Retard momentary retardations at K', B', &c. are equal to the accelerations at K and B, &c. the time of describing AC a is the same with that of describing AII a uniformly with the greatest velocity. That is, to the time of describing AC uniformly as AH a to AC, or as the circumference of a circle to the diameter. Therefore, &c. N. B. In this case of retarding forces it is convenient to represent them by ordinates K'L, BE, a D', lying on the other fide of the axis ACa; and to confider the areas bounded by these ordinates as subtractive from the others. Thus the square of the velocity at K' is expressed by the whole area DACK'L'D, the part C'K'L being negative in respect of the point DAC. This observation is general (See also OPTICS, nº 125, Encycl.)

Cor. 6. The time of moving along KC, the half of AC, by the uniform action of the force at A, is to that of describing AC a by the varied action of the force directed to C, and proportional to the distance from it, as the diameter of a circle to the circumference; for when the body is uniformly impelled along KC by the constant force IK, the square of the velocity acquired at C is represented by half the rectangle IKCH, and therefore it is equal to the velocity which the variable force generates by impelling it along AC (by the way, an important observation). The body will describe AC uniformly with this velocity in the same time that it is uniformly accelerated along KC. Therefore by

Cor. 5. the proposition is manifest.

Cor. 7. If two bodies describe AC and KC by the action of forces which are every where proportional to the distances from C, their final velocities will be proportional to the distances run over, and the times will

be equal.

For the squares of the final velocities are proportional to the triangles ADC, LKC, that is, to AC2, KC2, and therefore the velocities are as AC, KC. times of describing AC and KC uniformly, with velocities proportional to AC and KC, must be equal: and these times are in the same ratio (viz. that of radius to 1 of the circumference) to the times of describing AC and KC with the accelerated motion. Therefore,

Thus by availing ourselves of the properties of the circle, we have discovered all the properties or characters of a motion produced by a force always directed to a fixed point, and proportional to the dif-tance from it. Some of these are remarkable, such as the last corollary; and they are all important; for there are innumerable cases where this law of action obtains in Nature. It is nearly the law of action of a bowftring, and of all elastic bodies, when their change of figure during their mutual action is moderate; and it has been by the help of this proposition, first demonstrated in a particular case by Lord Brouncker and Mr Hnyghens, that we have been able to obtain precise measures of time, and consequently of actual motions, and consequently of any of the mechanical powers of Nature. It is for this reason, as well as for the eafy and perspicuous employment of the mathematical method of proceeding that we have felected it.

Instead of giving any more particular cases, we may obferve

203

made on the square of the velocity of both bodies. Of Accele-

o ceele observe in general, that if the intensity of the torce of r ig and proportional to any power whose index is n-1 of the 1 irding distance, and if a be the distance from the fixed point ces. at which the body begins to be accelerated, and a its distance from that point in any part of the motion, the velocity will be $= \sqrt{a^n - \kappa^n}$. This is very plain, because the increment CGHD of the area of fig. 16. which is also the increment of the square of the velocity, is $= x^{n-1}x$, and the area is $= x^n$; and the whole area, corresponding to the distance a, is an. Therefore the portion of the area lying beyond the distance x is $a^n - x^n$. This is as the square of the velocity, and therefore the velocity is as the square root $\sqrt{a^n - x^n}$ of this quantity.

This proposition, $f : \stackrel{\cdot}{=} v : v$, or $f \stackrel{\cdot}{=} \frac{v : v}{\cdot}$, is the

30th of the first book of Newton's Principia, and is perhaps the most important in the whole doctrine of dynamics, whether employed for the investigation of forces or for the explanation of motions. It furnishes the most immediate data for both purposes, but more especially for the last. By its help Sir Isaac Newton was able to point out the numerous difturbances of the planetary motions, and to separate them from each other; thus unravelling, as it were, that most intricate motion in which all are blended together. He has given a most wonderful specimen of its application in his Lunar

We now are able to explain all the puzzling facts which were adduced by Leibnitz and his partifans in support of their measure of the forces of bodies in motion. We see why four springs, equally bent, communicate but a double velocity, and nine springs but a triple velocity; why a bullet moving twice as fast will penetrate an earthen rampart to a quadruple depth,

1m vi-

This theorem also gives a most perspicuous explanation of the famous doctrine called confervatio virium vivarum. When perfectly elastic bodies act on each other, it is found that the fum of the masses multiplied by the squares of the velocities is always the fame. This has been fubftituted, with great encomiums, by the German philosophers in place of Des Cartes's principle, that the quantity of motion in the univerfe, estimated in one direction, remains always the fame. They are obliged, however, to acknowledge, that in the actions of perfectly hard bodies, there is always a loss of vis viva, and therefore have denied the existence of such bodies. But there is the fame loss in the mutual actions of all foft or ductile, or even imperfectly elastic, bodies; and they are miferably puzzled how to explain the fact: but both the confervatio and the amissio are necessary consequences of this theorem.

In the collision of elastic bodies, the whole change of motion is produced during the fhort time that the bodies are compressed, and while they regain their figure. When this is completed, the bodies are at the fame distance from each other as when the mutual action began. Therefore the preceding body has been accelerated, and the following body has been retarded, along equal spaces; and in every point of this space the accelerating and the retarding force has been equal. Confequently the same area of fig. 17. expresses the change

Therefore, if V and U are the velocities before collision, rating and and u the velocities after collision, of the two boForces. dies A and B, we must have $A \times V^2 - v^2 = B \times u^2 - V^2$, and therefore $A \times V^2 + B \times U^2 = A \times v^2 + B \times u^2$. But in the other class of bodies, which do not completely regain their figure, but remain compressed, they are nearer to each other when their mutual action is ended than when it began. The foremost body has .. been accelerated along a shorter space than that along

which the other has been retarded. The mutual forces have, in every instant, been equal and opposite. Therefore the area which expresses the diminution of the fquare of the velocity, must exceed the area expressing the augmentation by a quantity that is always the same when the permanent compression is the same; that is, when the relative motion is the fame. $A \times V^2 - v^2$ must exceed $B \times u^2 - U^2$, and $A \times V^2 + B \times U^2$ must exceed $A \times v^2 + B \times u^2$.

This same theorem is of the most extensive use in all practical questions in mechanic arts; and without it mechanics can go no farther than the mere statement of

Hermann, professor of mathematics at Pavia, one of History of the ornaments of the mathematical class of philosophers, no 95. is has given a pretty demonstration of this valuable propo. curious. sition in the Acta Eruditorum Lipsia for 1709; and fays, that having fearched the writings of the mathematicians with great care, he found himself warranted to fay, that Newton was the undoubted author, and boafts of his own as the first synthetical demonstration. The purpose of this affertion was not very apparent at the time; but long after, in 1746, when Hermann's papers, preserved in the town-house of Pavia, were examined, in order to determine a dispute between Maupertuis and Koenig about the claim to the discovery of the principle of least action, letters of Leibnitz's were found, requesting Hermann to fearch for any traces of this proposition in the writings of the mathematicians of Europe. Leibnitz was by this time the envious detractor from Newton's reputation; and could not but perceive, that all his contorted arguments for his doctrine received a clear explanation by means of this proposition, in perfect conformity to the usual measure of moving forces. Newton had discovered this theorem long before the publication of the Principia, and even before the discovery of the chief proposition of that book in 1666: for in his Optical Lectures, the materials of which were in his possession in 1664, he makes frequent use of a proposition founded on this (fee no 42.) We may here remark, that Hermann's demonstration is, in every step, the same with Dr Barrow's demonstration of it as a theorem merely geometrical, without speaking of moving forces (fee Lea. Geometr. xi. p. 85. edit. 16.), but giving it as an instance of the transformation of curves, which he calls scales of velocity, of time, of acceleration, &c. It is very true that Barrow, in thefe mathematical lectures, approached very near to both of Newton's discoveries, the fluxionary geometry, and the principles of dynamics; and the junto on the continent, who were his continual detractors, charge him with impudent plagiarism from Dr Barrow, and even fay that he has added nothing to the discoveries of his teacher. But furely Dr Barrow was the best judge of this mat-

Of Accele- ter; and fo far from refenting the use which Newton rating and has made of what he had taught him, he was charmed Retarding with the genius of the juvenis speciatissimus his scholar, and of his own accord gave him his profesiorial chair, and ever after lived in the utmost harmony and friendship with him. Nay, it would even appear, from some expressions in those very lectures, that Dr Barrow owed to young Newton the first thought of making such extensive use of motion in geometry. We recommend this work of Barrow's to the ferious perufal of our readers, who wish to acquire clear notions of the science of motion, and an elegant taste in their mechanical disquisitions. After all the cultivation of this science by the commentators and followers of Newton, after the Phoronomia of Hermann, the Mechanica of Euler, the Dynamique of D'Alembert, and the Mechanique Analytique of De la Grange, which are undoubtedly works of tran-Icendent merit and utility, the Principia of Newton will still remain the most pleasing, perspicuous, and elegant specimen of the application of mathematics to the science of univerfal mechanics, or what we call DYNAMICS.

The two fundamental theorems f t = v, and f s= v v, enable us to solve every question of motion accelerated or retarded by the action of the mechanical powers of nature. But the employment of them may be greatly expedited and simplified by noticing two or three general cases which occur very frequently.

Similar instants and points, what ?

These may be called similar instants of time, and similar points of space which divide given portions of time, and of space in the same ratio. Thus the middle is a similar instant of an hour or of a day, and is the similarly situated point of a foot or of a yard. The beginning of the an hour and of a day. The beginning of the 5th inch, and of the 2d foot, are fimilar points of a foot and of a

-106

Forces may be said to act similarly when their intenfions, what if ties in similar inflants of time, or in similar points of space, are in a constant ratio. Thus in fig. 17. when one body is impelled towards C from A, and another from K, each with a force proportional to the distance of every point of its motion from C, these forces may be faid to act fimilarly along the spaces AC and KC, or during the times represented by the quadrantal arches AFH, KNO. The following propositions on fimilar actions will be found very useful on many occasions; but we must premise a geometrical lemma.

ik, drawn from fimilar points I and i of the abscisses, are in the constant ratio of AE to ae; then the area ADHE is to the area adhe as the rectangle of AD

 \times AE to the rectangle $ad \times ae$.

For let each absciffa be divided into the same number of equal and very small parts, of which let CD and cd be one in each. Inscribe the rectangles CGID, cgid. Then because the number of parts in each axis is the fame, the lengths of the portions CD and cd will be proportional to the whole abscisses AD and a d. And because C and c are similar points, CG is to cg as AE is to ae. Therefore $CD \times CG : cd \times cg = AD$ A E: $ad \times ae$. This is true of each pair of corresponding rectangles; and therefore it is true of their Jums. But when the number of these rectangles is in-

creafed, and their breadth diminished without end, it is evi- Of Ac dent that the ultimate ratio of the fum of all the rectan- rating gles, fuch as CDHG to the fum of all the rectangles Retar cdhg is the same with that of the area ADHE to the area adbe, and the proposition is manifest.

If two particles of matter are similarly impelled during given times, the changes of velocity are as the times and as

the forces jointly.

Let the times be represented by the straight lines ABC (fig. 19.) and abc, and the forces by the ordinates AD, BE, CF, and ad, be, cf. Then if B and and b are fimilar inflants (fuppose the middles) of the whole times, we have BE: be = AD: ad. Therefore, by the lemma, the area ACFD is to acfd as $AC \times AD$ to $ac \times ad$. But these areas are proportional to the velocities (n° 72), and the proposition is demonstrated. For the same reason, the change of velocity during the time AB is to the change during a b as AB \times AD to $ab \times ad$.

Cor. 1. If the times and forces are reciprocally proportional, the changes of velocity are equal; and if the forces are inverfely as the times, the changes of velocity

If two particles be similarly urged along given spaces, the changes made on the squares of the velocities are as the

forces and spaces jointly.

For if AC (fig. 19.) and ac are the spaces along which the particles are impelled, and the forces are as the ordinates AD and a d, the areas ACFD and a c f d are as the changes on the squares of the velocities But these areas are as AC × AD, and ac × ad. Therefore, &c.

Cor. 2. If the spaces are inversely as the forces, the changes of the squares of the velocities are equal; and if these are equal, the spaces are inversely as the forces.

Cor. 3. If the spaces, along which the particles have been impelled from a previous state of rest, are directly as the forces, the velocities are also as the forces. For, because the changes of the squares of the velocities are as the spaces and forces jointly, they are in this case as the squares of the forces or of the spaces; but the changes of the squares of the velocities are in this cafe the whole squares of the velocities; therefore the squares of the velocities are as the squares of the forces, and the velocities are as the forces. N. B. This includes the motions reprefented in fig. 17.

If two particles be similarly impelled along given If there be two lines EFGH (fig. 18.), efgh, fore. spaces, from a state of rest, the squares of the times are lated to their abscisses AD, ad, that the ordinates IK, proportional to the spaces directly, and to the forces in-

versely.

Let ABC (fig. 19.) a bc be the spaces described,

Let ABC (fig. 19.) a bc be the spaces described, V, B express the velocity at B, and v, b the velocity

Let GHK and ghk be curves whose ordinates are inversely as the velocities at the corresponding points of the abscissa. These curves are therefore exponents of the times (no 99.) Then, because the forces act similarly, we have, by the last theorem, AC × AD : ac $\times a d = V^2$, B: v^2 , b, $= b b^2$: HB². Therefore HB : $bb = \sqrt{ac \times ad}$: $\sqrt{AC \times AD}$, and therefore in a constant ratio. Call this the ratio of m to n. But, fince the ordinates of the lines GHK, g h k are inversely as the velocities, the areas are as the times (11° 99.);

Accele and fince these ordinates are in the constant ratio of m ting and to n, the areas are in the ratio of $AC \times m$ to $ac \times n$. etarding Therefore (calling the times of the motions T and t), we have

 $T: t = m \land C: nac;$ and therefore $T^2: t^2 = m^2 \times A C^2: n^2 \times a c^2$. But $m^2: n^2 = a c \times a d: AC \times AD$. Therefore $T^2: t^2 = a \, \varepsilon \times a \, d \times AC^2: AC \times AD \times a \, c^2,$ Or $T^2: t^2 = a d \times AC : AD \times ac$. Or $T^2: t^2 = \frac{AC}{AD} : \frac{ac}{ad}$.

The attentive reader will observe that these three propositions give a great extension to the theorems which were formerly deduced from the nature of uniformly accelerated motion, or of uniform action of the forces, and were afterwards demonstrated to obtain in the momentary action of forces any how variable.

The first of the three propositions, $V: v = F \times T$: $f \times t$, is the extension of the theorem $f \times t = v$. fecond, V^2 : $v^2 = F \times S : f \times s$, is the extension of the theorem $f \times \dot{s} = v \dot{v}$. And the third, $T^2 : t^2 = \frac{S}{F} : \frac{s}{f}$, is the extension of $f = \frac{s}{(t^2)}$, or of $f \times (t^2) := \dot{s}$. These theorems hold true of all fimilar actions; and only for this reason, are true of uniformly accelerated motions, or uniform actions.

There remains one thing more to be faid concerning the action of accelerating forces. Their magnitude is gregate al acce- afcertained by their effect. Therefore that is to be confidered as a double force which produces a double quantity of motion Therefore when a body A contains twice the number of equal atoms of matter, and acquires the same velocity from the action of the force F that another body a, containing half the number of atoms, acquires from the action of a force f, we conceive F to be double of f. That this is a legitimate inference appears clearly from this, that we conceive the sensible weight of a body, or that pressure which it exerts on its supports, as the aggregate of the equal pref fure, of every atom, accumulated perhaps on one point; as when the body hangs by a thread, and, by its intervention, pulls at some machine. Without inquiring in what manner, or by what intervention, this accumulation of pressure is brought about, we see clearly that it refults from the equal accelerating force of gravity acting immediately on each atom. When this weight is thus employed to move another body by the intervention of the thread, which is attached to one point perhaps of that body, it puts the whole into motion, generating a certain velocity v in every atom, by acting uniformly during the time t. We conceive each atom to have fustained the action of an equal accelerating force,

CCS.

whose measure is - Without considering how this force is exerted on each atom, or by what it is immediately exerted, or how it is diffused through the body from the point to which the weight of the other body is applied by means of the thread; we still consider it as the aggregate of the action of gravity on each atom of that other body Moreover, attending only to the motion produced by it, and perhaps not knowing the weight of the impelling body, we measure it, as a mowing force, by confidering it as the aggregate of the SUPPL. Vol. I. Part II.

forces propagated to each atom of the impelled body, Of Acceleand measured by . If we know that the impelled Retarding body contains the number m of atoms, the aggregate of forces is $m = \frac{v}{t}$, or $\frac{m v}{t}$.

But fince we measure forces by the quantity of motion which they produce, we must conceive, that when the fame force is applied to a body which consists of n particles, and produces the velocity u, by acting uniformly during the same time t, the force n = 1 is equal to the

force $m = \frac{q}{t}$.

Sir Isaac Newton found it absolutely necessary, in Moving the disquisitions of natural philosophy, to keep this cir-force, mocumstance of acceleration clear of all notions of quantitive force, vis motrix, ty of matter, or other confiderations, and to contem- as diffinplate the affections of motion only. He therefore con-guished fidered $\frac{v}{}$ as the true original measure of accelerating learning

force, and $m = \frac{v}{t}$ as an aggregate. He therefore calls the aggregate a vis motrin, a moving force, measured by the quantity of motion that it generates. And he confines the term accelerating force to the quantity $\frac{1}{t}$, measured by the acceleration or velocity only. It would be convenient, therefore, also to confine the symbol f to $m = \frac{v}{t}$, and to retain the fymbol a for expressing the accelerating force $\frac{v}{t}$.

This appellation of motive force is perfectly just and fimple; for we may conceive it as the same with the accelerating force which produces the velocity m times v in one particle, by acting on it uniformly during the time t. This motion of one particle having the velocity m v, is the same with that of m particles having each the velocity'v.

If therefore a motive force f act on a body confishing of m particles, the accelerating force a is

Therefore the three last propositions concerning the fimilar, the uniform, or the momentary actions of moving forces, when expressed in the most general terms,

$$v' \stackrel{\cdot}{=} \frac{f}{mt'}.$$

$$v^{2i} \stackrel{\cdot}{=} \frac{f s'}{m}, \text{ or } v \stackrel{\circ}{v} = \frac{f \stackrel{\circ}{s}}{m}.$$

$$t^{3} \stackrel{\cdot}{=} \frac{m s'}{f}.$$

OF DEFLECTING FORCES.

WHEN we observe the direction of a body to change, Deflecting we unavoidably infer the agency of a force which acts forces. in a direction that does not coincide with that of the body's motion; and we may distinguish this circumstance by calling it a deflecting force. We have already shewn how to estimate and measure this deflecting force, by confidering it as competent to the

Of Deflec production of that motion which, when compounded ting Forces, with the former motion, will produce the new motion (n° 44.) Now, as all changes of motion are really compositions of motions or forces, it is evident that we shall explain the action of deflecting forces when we shew this composition

Alteration of deflections are continual, and pro lineal mo-

We may almost venture to say à priori, that all deflections must be continual, or exhibit curvilineal motions: for as no finite velocity, or change of velocity, can be produced in an inftant by the action of an acduce curvi- celerating force, no polygonal or angular deflection can be produced; because this is the composition of a finite velocity produced in an inftant. Deflective motions are all produced by the composition of the former motion, having a finite velocity, with a transverse motion contirually accelerated from a state of rest. Of this we can form a very distinct notion, by taking the simplest case of fuch accelerated motion, namely, an uniformly accelerated motion.

Example. Determination of the path,

Let a body be moving in the direction AC (fig. 20.) with any constant velocity, and when it comes to A, let it be exposed to the action of an accelerating force, acting uniformly in any other direction AE. This alone would cause the body to describe AE with a uniformly accelerated motion, so that the spaces AD, AE would be as the squares of the times in which they are described. Therefore, if AB be the space which it would have described uniformly in the time that it describes AD by the action of the accelerating force, and AC the space which it would have described uniformly while it describes AE by the action of the accelerating force-nothing more is wanted for ascertaining the real motion of the body but to compound the uniform motion in the direction AC with the uniformly accelerated motion in the direction AE. AD is to AE as the square of the time of describing AD to the square of the time of describing AE; that is, as the square of the time of describing AB to the square of the time of describing AC; that is, as AB2 to AC2 (by reason of the uniform motion in AC). This composition is performed by taking the fimultaneous points B, D, and the simultaneous points C, E, and completing the parallelograms ABFD, ACGE. The body will be found in the points F and G in the instants in which it would have been found at B and C by the uniform motion, or in D and E by the accelerated motion. In the same manner may be found as many points of the real path as we please. It is plain that these points will be in a line AFG, so related to AE that AD: AE = DF2: EG2; or so related to the original motion AC, that AB2: AC2 = BF: CG, &c. This line is therefore a parabola, of which AE is a diameter, DF and EG are ordinates, and which touches AC in

And of the this path.

Having thus ascertained the path of the body, we motion in can also afcertain the motion in that path; that is, the velocity in any point of it. We know, that the velocity in the point G is to the velocity of the uniform motion in the direction AC as the tangent TG is to the ordinate EG; because this is the ultimate ratio of the momentary increment of the arch AFG to the momentary increment of the ordinate EG. Thus is the velocity in every point of the curve determined. We have taken it for granted, that the line of projection touches the path, and that the direction in every point is that of the tangent, To suppose that the curve, in Of Def any portion of it, coincides with the tangent, is to fup. ting For pose that the body is not deflected; that is, is not acted on by a transverse accelerating force: And to suppose that the tangent makes a finite angle with any part of the path, is to suppose that the deflection is not continual, but by starts-both of which are contrary to the conditions of the case. No straight line can be drawn between the direction of the body and the fucceeding portion of the path, otherwife we must again suppose, that the deflection is subsultory, and the mo-

tion angular.

But while the investigation is so easy when the direction and intensity of the deflecting force in every point of the curve are known, the investigation of the deflecting force from the observed motion is by no means eafy. The observed curvilineal motion always arises from a composition of a uniform motion in the tangent with some transverse motion. But the same curvilineal motion may be produced by compounding the uniform motion in the tangent with an infinity of transverse motions; and the law of action will be different in these transverse motions according as their directions differ-We must learn, not only the intensity of the deslecting force, and the law of its variation, but also its direction iu every point of the curve. It is not easy to find gcneral rules for discovering the direction of the transverse force; most commonly this is indicated by extrinsic circumstances. The deflecting force is frequently observed to refide in, or to accompany some other body. It may be presumed, therefore, that it acts in the direction of the line drawn to or from that body; yet even this is uncertain. The most general rule for this investigation is to observe the place of the body at several intervals of time before and after its passing through the point of the curve, where we are interested to find its precise direction. We then draw lines, joining those places with the places of the tangent where the body would have been by the uniform motion only. We shall perhaps observe these lines of junction keep in parallel positions: we may be affured, that the direction of the transverse force is the same with that of any of these lines. This is the case in the example just now given of a parabolic motion. But when these lines change position, they will change it gradually; and their position in the point of contact is that to which their politions on both fides of it gradually approximate.

But all this is destitute of the precision requisite in philosophical discussion. We are indebted to Sir Isaac Newton for a theorem which ascertains the direction of the transverse force with all exactness, in the cases in which we most of all wish to attain mathematical accuracy, and which not only opened the access to those discoveries which have immortalised his name, but also pointed out to him the path he was to follow, and even marked his first steps. It therefore merits a very par-

ticular treatment.

If a body describes a curve line ABC, DEF (fig. Newton 21.) lying in one plane; and if there be a point S fofundame fituated in this plane that the line joining it with the tal theo e body describes areas ASB, ASC, ASD, &c. propor-rection of tional to the times in which the body describes the ar-destecting ches AB, AC, AD, &c. the force which deflects the force. body from rectilineal motion is continually directed to the fixed point S.

Let

Let us first suppose that the body describes the pog Forces lygon ABCDEF, &c. formed of the chords AB, BC, CD, DE, EF, &c. of this curve: and (for greater fimplicity of argument) let us cousider areas described in equal successive times; that is, let us suppose that the triangles ASB, BSC, CSD, &c. are equal, and deferibed in equal times. Make Bc = AB, and draw

Had the motion AB fuffered no change in the point eas = to B, the body would have described B c in the equal motimes ment fucceeding the first: but it describes BC. The body has therefore been deflected by an external force; and BC is the diagonal of a parallelogram (n° 45. 46.), of which B c is one fide, and c C is another. The deflecting force will be discovered, both in respect of direction and intenfity, by completing the parallelogram BcCb. Bb is the space which the deflecting force would have caused the body to describe in the time that it describes Bc or BC. Because Bc is equal to BA, the triangles BS c, BSA are equal. But (by the BA) of the motion BSA is equal to BSC. Therenature of the motion) BSA is equal to BSC. fore the triangles BSC and BS c are equal. They are also on the same base BS; therefore they lie between the same parallels, and Cc is parallel to SB. But c C is parallel to B b. Therefore B b coincides with BS, and the deflecting force at B is directed toward S. By the same argument, the deflecting force at the angles D, E, F, &c. is directed to S.

Now, let the fides of the polygon be diminished, and their number increased without end. The demonstration remains the fame; and continues, when the polygon finally coalesces with the curve, and the deflection is

continual.

When areas are described proportional to the times, equal areas are described in equal times; and therefore the deflection is always directed to S. Q. E. D.

The point S may, with great propriety of language, be called the CENTRE OF DEFLECTION, OF THE CEN-TRE OF FORCES; and forces which are thus continually directed to one fixed point, may be diftinguished from other deflecting forces by the name CENTRAL

The line joining the centre of forces with the body, and which may be conceived as a stiff line, carrying the us vec-body round, is usually named the RADIUS VECTOR.

The converse of this proposition, viz. that if the deral for flecting forces be always directed to S, the motion is roduce performed in one plane, in which S is fituated, and pro. areas are described proportional to the times—is easily onal to demonstrated by reversing the steps of this demonstration. The motion will be in the plane of the lines SB and Bc; because the diagonal BC of the parallelogram of forces is in the plane of the sides. Areas are defcribed proportional to the times; for Cc being parallel to SB, the triangles SCB and ScB are equal; and therefore SCB and SAB are equal, &c. &c.

Cor. 7. When a body describes areas round S procity is portional to the times, or when it is continually deflecfely as ted toward S, or acted on by a transverse force directed to S, the velocities in the different points A and E of the the curve are inversely proportional to the perpendiculars Sr and St, drawn from the centre of forces to the tangents in those points; that is, to the perpendiculars from the centre on the momentary directions of the motion: For fince the triangles ASB, ESF are equal,

their bases AB, EF are inversely as their altitudes Sr, Of Deflec-But these bases, being described in equal times, ting Forces, are as the velocities; and they ultimately coincide with the tangents at A and E.

Cor. 2. If B a and F be drawn perpendicular to SA and SE, we have $S \times B = SE \times F$, and $SA : SE = F : B_{\alpha}: For SA \times B_{\alpha}$ is double of the triangle BSA, and SE x F : is double of the equal triangle SFE.

Cor. 3. The angular velocity round S, that is, the Angular vemagnitude of the angle described in equal times by the locity is inradius vector, is inverfely proportional to the square of verfely as the distance from S. For when the arches AB, EF the square are diminished continually, the perpendiculars B a and tance from E, will ultimately considerable before the standard standard from the standard standard from the standard standard from the standard from t F & will ultimately coincide with arches described round the centre S with the radii SB and SF. Now the magnitude of of forces. an angle is proportional to the length of the arch which

measures it directly, and to the radius of the arch inverfely. In any circle, an arch of two inches long meafures twice as many degrees as an arch one inch long; and an arch an inch long contains twice as many degrees of a circle whose radius is twice as short. Therefore, ultimately, the angle ASB is to the angle ESF as B α to F $_{\epsilon}$, and as SF to SB jointly; that is, as B α × SF to F $_{\epsilon}$ × SB. But B α : F $_{\epsilon}$ = SE : SA (Cor. 2.). Therefore ASB : ESF = SE \times SF : SB \times SA, = ultimately SE2: SB2.

This corollary gives us an oftenfible mark, in many very important cales, of the action of a deflecting force being always directed to a fixed point. We are often able to measure the angular motion when we cannot

measure the real velocities.

Having thus discovered the chief circumstances which intimate enable us to ascertain the direction of the deflecting connection force, we proceed to investigate the quantity of this de of tynamics flective determination in the different points of an the flective determination in the different points of a curvi higher geolineal motion. This is a more difficult talk. The mo-metry. mentary effect of the deflecting force is a small deviation from the tangent; and this deviation is made with an accelerated motion. The law of this acceleration regulates the curvature of the path, and is to be determined by it. We may be allowed to observe by the way, that it appears clearly from the form in which Newton has prefented all his dynamical theorems, that we are indebted to these problems for the immense improvement which he has made in geometry by his invention of fluxions. The purposes he had in view singgested to his penetrating mind the means for attaining them; and the connection between dynamics and geometry is so intimate, that the same theorems are in a manner common to both. This is particularly the case in all that relates to curvature. Or shall we say that the geometry of Dr Barrow fuggested the dynamical theorems to Newton? We have feen how the curvature of a parabola is produced by a force acting uniformly. The momentary action of all finite forces may be confidered as uniform; and therefore the curvature will be that of fome portion of fome parabola; but it will be difficult to determine the precife degree without some faither We are best acquainted with the properties of the circle, and will have the clearest notions of the curvature of other curves by comparing them with circles.

The curvature of a circular arch of given length is Measure of fo much greater as its radius is shorter; for it will con-curvature. tain so many more degrees in the fame length; and

3 Y 2

re of

ces.

540

Of Deflec- therefore the change of direction of its extremities is fo ting Forces much greater. Curvatures may always be measured by the length of the arch directly and the radius in-

Evolution tion of curves.

Suppose a thread made fast at one end of a material and involve curve ABCD (fig. 22.) and applied to it in its whole length. Taking hold of its extremity D, unfold it gradually from the curve DCBA; the extremity D will describe another curve Dcba. This geometrical operation is called the Evolution of curves, and D c b a is called the EVOLUTE of DCBA, which is called the INVOLUTE of Dcba. Perhaps this denomination has been given from the genefis of the area or surface contained by the two lines, which is folded up and unfold. ed fomewhat like a fan. When the describing point is in b, the thread b B is, undoubtedly, the momentary radius of a circle ebf, whose centre is B, the point of the involute which it is just going to quit. The momentary motion of b is the fame, whether it is describing an arch of the evolute passing through b, or an arch of a circle round the centre B. The same line bt, perpendicular to the thread bB. touches the circle ebf and the curve Dba in the point b. This circle ebf must lie within the curve Dba on the side of bB toward a; because on this side the momentary radius is continually increasing. For fimilar reasons, the circle ebf lies without the curve on the other fide of b B. Therefore the circle ebf both touches and cuts the curve D b a in the point b. Moreover, because every portion of the curve between b and D is described with radii that are shorter than b B, it must be more incurvated than any portion of the circle ebf. For fimilar reasons, every portion of the curve between b and a must be less incurvated than this circle; therefore the circle has that precise degree of curvature that belongs to the curve in the point b; it is therefore called the Equicurve Circle, or the Circle of Curvature, curvature, and B is called the centre, and B b the RADIUS OF CURVATURE. It is easy to perceive that no circle can be described which shall touch the curve in b, and come between it and the circle ebf; for its centre must be in some point i of the radius b B. If i b be less than B b, it must fall within the curve on both sides of b, and if ib is greater than Bb, the circle must fall without the curve on both fides of B b. The circle e bf lies closer to the curve, has closer contact with it, than any other, and has therefore got the whimfical name of OSCULATING CIRCLE; and this fort of contact was called OSCULATION.

This view of the genefis of curve lines is of particular use in dynamical discussions. It exhibits to the eye the perfect famenels of the momentary motion, and therefore of the momentary deflection, in the curve and in the equicurve circle, and leaves the mind without a doubt but that the forces which produce the one will produce the other. A great variety of curves may be described in this way. If perpendiculars be drawn to the curve D b a in every point, they will interfect each other, each its immediate neighbour, in the circumference of the curve DBA: and geometry teaches us how to find the curve DBA which shall produce the curve D ba by evolution (fee EVOLUTION and INVO-

LUTION, Supplement.).

It is a matter worthy of remark, that the path of a body that is deflected from rectilineal motion by a fi-

nite force, varying according to any law whatever, may Of Def always be defcribed by evolution. This includes al-ting Fo most every case of the action of destecting forces; none being excepted but when, by the opposite action of different forces, the body is in equilibrio in one fingle point of its path.

Our task is now brought within a very narrow compass, namely, to measure the deflection in the arch of a

Had the motion represented in fig. 21. been polygonal, it is plain that the deflecting force in the point B is to that in the point E as the diagonal Bb of the parallelogram ABC b to the diagonal Ei of the parallelogram DEFi; therefore let ABCZY be a circle passing through the points A, B, and C, and let the radius vector BS cut the circumference in Z; draw AZ, CZ, and the diagonal AC, which necessarily bifects and is bifected by the diagonal B b. The triangles b BC and CBZ are similar; for the angle C b B is equal to the alternate angle AB b or ABZ, which is equal to the ACZ, standing on the same chord AZ. And the angle CB b, or CBZ, is equal to CAZ, standing on the fame chord CZ; therefore the remaining angle b CB is equal to the remaining angle AZC; therefore Z λ is to AC as BC to B b, and B b

 $\frac{AC \times BC}{AZ}$ In like manner $E_i = \frac{DF \times EF}{Dz}$.

Now let the points A and C continually approach, and ultimately coalesce with B; it is evident that the circle ABCZY is ultimately the equicurve or coinciding circle at the point B, and that AS ultimately coalesces with, and is equal to, BS, and that AC×BC is ultimately 2BC2; therefore ultimately Bb: Ei = $\frac{2BC^2}{BZ}: \frac{2EF^2}{E z}, \text{ or } = \frac{BC^2}{\frac{1}{2}BZ}: \frac{EF^2}{\frac{1}{2}E z}$

Now BC and EF, being described in equal times, Measur are as the velocities: B b and E i are the measures of defled the velocities which the deflective forces at B and Eforces. would generate in the time that the body describes BC or EF, and are therefore the measures of those forces. They are as the squares of the velocities directly, and inverfely as those chords of the equicurve circles which have the directions of the deflection.

Observe, that B b or E i is the third proportional to half of the chord and the arch described; for B b : BC

 $= BC : \frac{BZ}{2}$

It is evident, that as the arches AB, BC, continually diminish, AC is ultimately parallel to the tangent Br, and BO is equal to the actual deflection from the tangent. The triangles BOC and AOZ are fimi-

lar, and BO = $\frac{OC^2}{OZ}$, or ultimately = $\frac{BC^2}{BZ}$ measure the forces by the actual deflections, because they are the halves of the measures of the generated velocities; and we may fay that

The actual momentary deflection from the tangent is a Meal third proportional to the deflective chord of the equi-deflect curve circle and the arch described during the moment.

Either of these measures may be taken, but we must Cauti take care not to confound them. The first is the most proper, because the change produced on the body (which is the immediate effect and measure of the force) is the determination, left inherent in it, to move with

Circle of Equicurve' circle.

Deflec- a certain velocity. This is the measure also which we Forces obtain by means of the differential or fluxioutry calculus; but the other measure must be obtained when our immediate object is to mark the actual path of the body. What is now delivered coincides with what was more briefly stated in Astronomy, Suppl. no 16. and is repeated in this place, because the steps of this demonstration, which is Newton's, fo naturally terminate in the equicurve circle, and give at once the immediate measure of the deflecting force: at the same time the reader must perceive that this measure does not depend on the force being always directed to one centre; it is enough that the two fides of the polygon, in immediate fuccession, are described in equal times. This is necessary in order that ABCb may be a parallelogram, and that the diagonals AC and B b may mutually bifect each other.

Thus have we obtained a measure of destecting force, and, in the most important cases, a method of discovering its direction. It only remains to point out the relation between the intensity of the force, the curvature of the path, and the velocity of the motion. These three circumstances have a necessary connection; for we fee that the intenfity is expressed by certain values

of the other two in the formula $f = \frac{1}{2} \frac{1}{C \cdot C \cdot C \cdot C}$ or f

 $\frac{2 BC^2}{BZ}$. The deflective velocity B b is acquired in the time that the body deferibes BC; therefore the deflective velocity is to the velocity in the curve as B bto BC. The velocity B b is acquired by an accelerated motion along BO; for while, by progressive motion, the body describes BC, it deslects from the tangent through a space equal to the half of B b, became the momentary action of the deflecting force may be confidered as uniform. The progressive velocity BC may be generated by the fame force, uniformly acting through a space greater than BC; call this space x. The spaces along which a body must be uniformly impelled in order to acquire different velocities, are as the squares of those velocities; therefore Bb2: BC2 = Bo:x; but $Bb:BC = BC: \frac{1}{2}BZ$; therefore Bb^2 : $BC^2 = Bb: \frac{1}{3}BZ$, and $Bb: \frac{1}{3}BZ = Bo: \kappa$, and $Bb: Bo = \frac{1}{2}BZ: x$; but Bo is $\frac{1}{2}$ of Bb; therefore x is \frac{1}{3} of BZ; that is,

The velocity in any point of a curvilineal path, is that which the deflecting forces in that point would generate in the body by impelling it uniformly along one fourth part of the deflective chord of the equicurve circle. If the velocity increase, the chord of the equicurve circle must inerease; that is, the path becomes less incurvated. If the force be increased, the curvature will also increase,

for the chord of curvature will be lefs.

There is another general observation to be made on the velocity of a curvilineal motion, which greatly af-

fifts us in our investigations.

If a body describes a curve by the action of a force always directed to a fixed point, and varying according to notion whatever of the distances from that point, a not to and if another body, asked on by the same centripetal centre. force, move toward the centre in a straight line, and if in any one case of equal distances from the centre of force the two bodies have equal velocities, they will have equal velocities in every other case of equal distances from the

Let one body be impelled from A (fig. 23.) toward Of Deflec-C along the straight line AVDEC, and let another be ting Forces. deflected along the curve line VIK k. About the centre C describe concentric arches ID, KE, very near to each other, and cutting the curve in I and K, and the line AC in D and E; draw IC, cutting KE in N, and draw NT perpendicular to the arch IK of the curve, and complete the parallelogram ITNO. Let the bodies be supposed to have equal velocities at I and

Then, because the centripetal forces are supposed to be the same for both bodies when they are at equal distances, the accelerating forces at D and I may be represented by the equal lines DE and IN; but the force IN is not wholly employed in accelerating the body along the arch IK, but, acting transversely, it is partly employed in incurvating the path. It is equivalent to the two forces IO and IT, of which only IT accelerates the body. Now IKN is a right angled triangle, as is also the triangle INT; and they are similar; therefore IN: IT = IK: IN, or DE: IT = IK: DE; that is, the force which accelerates the body along DE is to the force which accelerates the body along IK as the space IK is to the space DE; therefore (nº 86.) the increment of the square of the velocity acquired along DE is equal to the increment of the square of the velocity-acquired along IK. But the velocities at D and I were equal, and confequently their fquares were equal; and these having received equal increments, therefore the squares of the velocities at E and K are equal, and the velocities themselves are equal. And since this is the case in all the corresponding points of the line AC and the curve VIK, the velocities at all equal distances from C will be equal.

It is evident that the conclusion will be the same, if the bodies, inflead of being accelerated by approaching the centre in the straight line AC, and in the curve VIK, are moving in the opposite directions from E to A, or from I to V, and are therefore retarded by the

centripetal force.

Cor. Hence it follows, that if a body be projected Retarded from any point, such as V, of the curve, in a line tend-curvilineal ing straight from the centre, with the velocity which it motion alhad in that point of the curve, it would go to a diffance companied VA, fueh, that if it were impelled along AV by the cen- by recess tripetal force, it would acquire its former velocity in the from the point V; also in any point between V and A it will centre. have the same velocity in its recess from the centre that

it has there in its approach to the centre.

The line BLFG, whose ordinates are as the intensities of the centripetal force in A, V, D, E, or in A, V, I, K, may be called the SCALE OF EXPONENT of force; the areas bounded by the ordinates AB, VI., DF, EG, &c. drawn from any two points of the axis, are as the fquares of the velocity acquired by acceleration along the intercepted part of the axis, or in any curvilineal path, while the body approaches the centre, or which are loft while the body retires from it. When we can compute thefe areas we obtain the velocities (fee no 102.).

We are now in a condition to folve the chief problem in the science of dynamics, to which the whole of it is, in a great measure, subservient. The problem is

Let a body be projected with a known velocity from

blem of centril etal -forces.

Of Deflec- a given point and in a given direction, and let it be unting Forces der the influence of a mechanical force, whose direction, intenfity, and variation, are all known: it is required to Inverse pro- determine its path, and its motion in this path, for any

This problem is susceptible of three distinct classes of conditions, which require different investigation.

1. The force may act in one constant direction; that

2. The force may be always directed to a fixed

3. It may be directed to a point which is continually

changing it place.

1. When the force acts in parallel lines, the problem is folved by compounding the rectilineal accelerated motion which the force would produce in its own direction with the uniform motion which the projection alone would have produced. The motion must be curvilineal, when the accelerating force is transverse, in any degree whatever, to the projectile motion; and the curvilineal path must be concave on that side to which the deflecting force tends; for the force is supposed to act incessantly. The place of the body will be had for any time, by finding where the body would have been at the end of that time by each force acting alone, and by completing the parallelogram. Thus, suppose a body projected along AB (fig. 20.) while it is continually acted on by a force whose direction is AD. Let D and B be the places where the body would be at the end of a given time. Then the body will, at the end of that time, be in F, the opposite angle of the parallelogram ABFD. But it has not described the diagonal AF, because its motion has been curvilineal, as we shall find by determining its place at other instants of

The velocity in any point F is found by first determining the velocity at D, and making DT to DF as the velocity at D to the velocity at B (that is, the velocity of projection, because the motion along AB is uniform). Then draw IF. Then AB is to TF as the constant velocity of projection to the velocity at F. We have feen already (no 112-119.) that TF is a tangent to the curve in F. Hence we may determine the velocity at F in another way. Having determined the form of the path in the way already described, by finding its different points, draw the tangent Fd, cutting the line DA in d. Then the/velocity at A is to that at F as AB to dF. Hence also we see, that the velocities in every point of the curve are proportional to the portion of the tangents at those points which are intercepted between any two lines parallel to AD.

Either of these methods for ascertaining the velocity, in this case of parallel deflections, will in general be eafier than the general method in no 121. by the equi-

curve circle.

It was thus that Galileo discovered the parabolic mo-

tion of heavy bodies.

Inverse problem of centripetal

2. We must consider the motions of bodies affected by centripetal or centrifugal forces, always tending to one fixed point. This is the celebrated inverse problem of centripetal forces, and is the 42d proposition of the first book of Newton's Principia. We shall give the solution after the manner of its illustrious author; because it is elementary, in the purest sense of the word,

keeping in view the two leading circumffances, and Of Del these only, namely, the motion of approach and recess ting Fo from the centre, and the motion of revolution. By this judicious process, it becomes a pattern by which more refined, and, in some respects, better folutions should be modelled. At the same time we shall supply fome steps of the investigation which his elegant conciseness has made him omit.

Let a body, which tends to C (fig. 24.) with a force proportional to the ordinates of the exponent BLFG, having the axis CA, be projected from V in the direction VQ, with the velocity which the centripetal force would generate in it by accelerating it along AV. It is required to determine the path or orbit VIKI of the body, and its place I in this orbit, at the end of the af-

figned time T?

Suppose the thing done, and that I is the place of the body. About the centre C, with the distances CV and CI, describe the circles YV and ID. Draw CIX to the circumference, and draw the ordinate DF of the exponent of forces, producing it toward x, and produce the ordinate VI. toward a. Let V t be the distance to which the body would go along the tangent VQ in the time T, and join tC. Let this be supposed done for every point of the curve. Let aik and axy be two curves fo related to the curve VIK, that the ordinate DF cuts off an area VaiD equal to the orbital fector VCI, and an area Vax D equal to the circular fector VCX.

Then, because the velocity of projection is given, the distance V t is known, and the area of the triangle VCt. But this is equal to the area VCI, by the laws of central forces (no 115.). Therefore the area VaiD is given. Also, because the area VCI increases in the proportion of the time, the area VaiD increases at the same rate. Therefore, having these subsidiary curves aik, axy, the problem is folved as follows:

Draw an ordinate Di, cutting off an area Vai D proportional to the time, and describe a circle DIR. Then draw a line CX, cutting off a fector VCX, equal to the area Vax D cut off by the ordinate Dix. This line will cut the circle DR in the point I, which is the

point of the orbit that was demanded.

But the chief difficulty of the problem confifts in the description of the two subfidiary curves a i k and a x y, into which the lines VIK and VXY are transformed. We attain this construction by resolving the motion in the arch of the orbit into two motions, one of which is in the direction of the transverse force, or of the radius vector, and the other is in the direction of revolution, or perpendicular to the radius.

Let V k and IK be two very small arches described in equal moments, and therefore ultimately in the ratio of the velocities in V and I (no 73.). Describe the circle KE, cutting IC in N. Draw KC and kC, and

k n perpendicular to VC.

The element ICK of the orbit is $=\frac{\text{IC} \times \text{KN}}{2}$, or to I IC × KN. This is equal to the element Dik E of the area V ai D, or to D $i \times$ DE, or to D $i \times$ IN. Therefore IN: KN = \frac{1}{2} IC: Di, or 2 IN: KN = IC:D i, and D $i = \frac{IC \times KN}{2 IN}$

Now let A lfg h be the exponent of the velocities,

Deflect that is (n° 86.), let V/2 be to Df2 as ABLV to gument, and that the final values of Di and D a might Of Deflect Forces. ABFD, or $Vl: Df = \sqrt{\overline{ABLV}} : \sqrt{\overline{ABFD}}$. Make V v and I i in the tangents respectively equal to V l and Df. Draw vu and io perpendicular to VC and IC, and vm perpendicular to LV produced. Let mrz be an equilateral hyperbola, having VC, ZC, for its assymptotes, and cutting FD produced in r. Then the ordinates Vm, Dr, are inverfely proportional to CV, CD, or Vm: Dr = CD: CV, = CI: CV. But because the momentary sectors VC k and ICK are equal, kn : KN = CI : CV. Therefore,

Vm: Dr = kn: KNVv:Vm=Vk:kn $\operatorname{I}i(\operatorname{or} \operatorname{D}f): \operatorname{V}v = \operatorname{IK}: \operatorname{V}k$ therefore Ii: Dr=IK: KN

Ii: io = 1K: KN, by fim. triang. Therefore Dr = io, and io: Vm = VC: CI. Alfo, by fimilarity of triangles, Io: io = IN: KN,

and 2 I o: io = 2 IN: KN.

Now it was shewn, that in order that the space Dik E may be equal to the space ICK, we must have

$$2 \text{ IN} : \text{KN} = \text{IC} : \text{D} i$$
or
$$2 \text{ I} o : io = \text{IC} : \text{D} i$$
but
$$io : \text{V} m = \text{VC} : \text{IC}$$
therefore 2 I o : V m = VC : D i
$$\text{VC} \times \text{V} m$$

and D $i = \frac{\text{VC} \times \text{V } m}{2 \text{ I } o}$

Having obtained D i, we easily get D x; for the ultimate ratio of ICK to XCY is that of IC² to VC². Therefore make

 $IC^2: VC^2 = Di: Dx.$

Thus are the points of the two fubfidiary curves aik, axy, determined.

The rectangle $VC \times Vm$ is a constant magnitude; and is given, because VC is given, and V m is the given velocity V /, diminished in the ratio of radius to the sine

of the given angle CVO.

But the line 2 I o is of variable magnitude, but it is also given, by means of known quantities. I o2 is $= Ii^2 - io^2, = Df^2 - Dr^2, \text{ and } Io = \sqrt{Df^2 - Dr^2}.$ Moreover, $Df^2 = ABFD$, and $Dr^2 = \frac{VC^2 \times Vm^2}{IC^2}$.

Therefore $2Io = 2\sqrt{ABFD - \frac{VC^2 \times Vm^2}{IC^2}}$, ex.

pressed in known quantities, because ABFD is known

from the nature of the centripetal force.

Let the indeterminate distance CI or CD be = x, and let the ordinate DF, expressing the force, be y. Let VC be a, and V m be c, and let ab be a rectangle equal to the whole area of the exponent of force lying between the ordinate AB and the ordinate CZ, fo that ab - /yx may represent the indeterminate area ABFD.

We have D
$$i = \frac{ac}{2\sqrt{ab-\int y\dot{x}-\frac{a^2c^2}{x^2}}}$$

and D $x = \frac{a^3c}{2x^2\sqrt{ab-\int y\dot{x}-\frac{a^2c^2}{x^2}}}$.

REMARK. We have hitherto supposed that the velocity of projection is acquired by acceleration along AV. But this was merely for greater simplicity of ar-

be easier conceived. In whatever way the velocity is ting Forces, acquired, it will still be true, that when in any point V we make V l to V m as the momentary increment V k of the arch is to the perpendicular k n on the radius vector, we shall have in every other point, such as I, the line Df to the line Dr as the increment IK of the arch to KN. And in the final equation Df will still be expressed by $\sqrt{ab-\int_{yx}}$.

Cor. 1. The angle which the path of the projectile

makes with the radius vector is determined by this folution; for I i is to io as radius to the fine of this

angle; which fine is therefore $=\frac{ac}{x\sqrt{ab-\int_{yx}^{x}}}$

Cor. 2. When the magnitude $\frac{ac}{x}$ is equal to

 $\sqrt{ab-\int_{yx}}$, the path is perpendicular to the radius vector, and the body is a tone of the apfides of its orbit, and termined; begins to recede from the centre after having approach-

ed to it, or begins to approach after having receded.

Cor. 3. The curvature of the orbit VIK is also de-And curvatermined in every point; for the curvature of any lineture. is inverfely as the radius of the equicurve circle, and this is to the chord which passes through C as radius to the fine of the angle CI i. Because the velocity in any point I is = VABFD, and is equal to what the centripetal force at I would produce, by impelling the body along 4th of the deflective chord of the equicurve circle,

we have this chord = $4 \frac{ABFD}{DF}$. Or we obtain it by

taking a third proportional to the momentary deflection and the momentary arch of the curve, or by other proceffes of the higher geometry, all proceeding on the quantities furnished in this investigation.

Such is the folution of this celebrated problem given Newtonthe by Sir Ifaac Newton, who may justly be called the in inventor. ventor of the science of which it is the chief result, as well as of the geometry, by help of which it is profecuted. For we cannot give this glory to Galileo; for his simple problem of the motion of bodies affected by uniform and parallel gravity, however just and elegant his folution may be, was peculiar; and the fame must be said of Mr Huyghens's doctrine of centrifugal forces. Besides, these theorems had been investigated by Newton several years before, sut mathesi facem preferente, as corollaries which he could not pass unnoticed, from his general method. This is proved by letters from Huyghens. Newton's investigation is extremely, but elegantly, concife, and is one of the best exertions of his fagacious mind.

Whether we consider this problem as a piece of mere History of mathematical speculation, or attend to its confequences, this prowhich include the whole of the celeftial motions in all blem. their extent and complication, we must allow it to be highly interesting, and likely to engage much attention in the period of ardent inquiry which closed the last century. Accordingly, it was no fooner known, by the publication of the Mathematical Principles of Natural Philosophy in 1686, than it occupied the talents of the most eminent mathematicians; and many folutions were published, fome of which differ confiderably from Newton's; fome are more expeditious, and better fitted for computation. Of these, the most remarkable

Of Deflect for originality and ingenuity are those of de Moivre, ting Forces. Hermann, Keill, and Stewart. The last differs most from the methods purfued by others. M'Laurin's propositions on this subject, and in that part of his sluxions which treats of curvature, are highly valuable, classing the chief affections of curvilineal motions geometrically, as they are fuggested by the fluxionary method; and then shewing, in a very instructive manner, the counection between these mathematical affections of motion and the powers of nature which produce them. part of his excellent work is a fine example of the real nature of all inquiries in dynamics; shewing that it differs from geometry little, more than in the language, in which the word force is substituted for acceleration, retardation, or deflection. We recommend the careful perufal of these propositions to all who wish to have clear conceptions of the subject. Dr John Keill and Dr Horseley (bishop of Rochester) have given particular treatifes on the motions of bodies deflected by centripetal forces inverfely proportional to the cubes of the diftances; induced by the fingular motions which refult from this law of action, and the multitude of beautiful propositions which they suggest to the mathematician. Newton, indeed, first perceived both of these peculiarities, and has begun this branch of the general problem. He first demonstrated the description of the logarithmic and hyperbolic spirals, and indicated a variety of curious recurring elliptical fpirals, which would be deferibed by means of this force, and shewing that they are all susceptible of accurate quadrature. Several of those authors affect to confider their folutions as more perfect than Newton's, and as more immediately indicating the remarkable properties of fuch motions; and also affect to have deduced them from different and original principles. But we cannot help faying, that their claims to superiority are very ill founded; there is not a principle made use of in their folutions which was not pointed out by Newton, and employed by him. The appearance of originality arises from their having taken a more particular concern in fome general property of curvilineal motions; fuch as the curvature, the centrifingal force, &c. and the making that the leading step of their process. But Newton's is still the best; because it is strictly elementary, aiming at the two leading circumstances, the motion to or from the centre, and the motion of revolution round that centre. To thefe two purposes he adapted his two subsidiary curves. This procedure became Newton, paier, et rerum inventor, who was teaching the world, and who might fay,

> Avia Pieridum peragro loca, nullius ante Trita pede—

Singular hoast of John Bernoulli. Is it not furprifing, that 25 years after the publication of Newton's *Principia*, a mathematician on the continent should publish a folution in the Memoires of the French academy, and boast that he had given the first demonstration of it? Yet John Bernoulli did this in 1710. Is it not more remarkable that this should be precisely the folution given by Newton, beginning from the same theorem, the 40th I. Prin. following Newton in every step, and using the same subsidiary lines? Yet so it is. Bernoulli actually reduces the whole

to two functions; namely, $\int ab - \int \phi \dot{x}$ and $\frac{a^2c}{\sqrt{abx^4-\int px^4-a^2c^2x^2}}$; which last is plainly the fame with Newton's $\frac{Q \times CX^2}{A^2 \sqrt{ABDF} - Z^2}$; because Newton's $\frac{Q}{A}$ is the same with $\frac{ac}{x}$, and Newton's $A^2\sqrt{ABFD-Z^2}$ is the fame with $x^2/ab-\int \hat{x}$ $\frac{a^2 c^2}{c^2}$, which Bernoulli has changed (apparently to hide the borrowing) into $\int a b x^4 - \int \phi x^4 x - a^2 c^2 x^2$. This publication of Bernoulli is perhaps the most impudent piece of literary robbery, for theft is too mild a term, that has ever appeared; and is the more deferving of fevere reprehension, because it is full of reflections on the simple and supremely elegant method of Newton. It is hardly conceivable that a person of Bernoulli's confummate mathematical knowledge was fo much blinded by the mechanical procedure of the fymbolical calculus (which indeed is rarely accompanied by any ideas of the fubject in hand) as not to perceive the perfect sameness of his folution. No; he shews, from time to time, that the physical ideas of motion and force were present to his mind; for he affects to fhew, that all Newton's brightest discoveries, such as the proportionality of the

Bernoulli's chief boast in this differtation is, that now philosophers may be affired that the planets will always describe conic sections; a truth of which they had not as yet received any proof: because, says he, Newton's argument for it in the corollary of the 13th proposition is inconclusive, and because he had not been able to accommodate his demonstration of the 41st and 42d proposition to the particular case of the planetary gravitation. Two affertions that border on insolence. Newton's demonstration in the corollary of the 13th proposition is just, founded on the principle on which the very demonstration of the 42d, adopted by Bernoulli, proceeds, and without which that demonstration is of no force; namely, that a body, in given circumstances of fituation, velocity, direction, and centripetal force, can describe no other figure than what it really describes. Newton did not accommodate the demonstration of the 42d proposition to the planetary motions, because he had already demonstrated the nature of their orbits; but mentions the case of a force proportional to the reciprocal of the cubes of the diftance; not as a deduction from the 42d, but because it was not a deduction from it, and admitted a very fingular and beautiful investigation by methods totally and essentially different.

areas and times, &c. flow as corollaries from his proce-

Bernoulli also fays, that Newton's solution does not give us the notion of a continuous path, as his own does, but only informs us how to ascertain points of this path. This is the boldest of all his assertions. Bernoulli uses the differential calculus. It is the effential character of this calculus that it exhibits, and can exhibit, nothing

elusion. but detached points. This is undeniable. And this has been objected to Newton's first proposition. But Newton's fluxionary. geometry, of which the calculus exhibits only elements (being the fame with the differential), fupposes the continuity of all magnitudes; and when applied to dynamics, is no fubflitution whatever, but the ipfa corpora. This geometry offered itself to the mind of Newton, the accomplified and darling scholar of Barrow, whose geometry flashed on Newton's mind as the torch which was to shew him the steps of this yet untrodden path.

We trust that our readers will not be displeased with our repeated endeavours to defend our great philofoplier from the injurious attacks that have been made on him. During his own illustrious life, while he was diffusing light and knowledge around him, and never contended for fame, happy in being the instructor of mankind, he was injured by those who envied his reputation, while they derived their chief honours from being his best commentators. Now, fince he has left this world, he has been more grofsly injured by those who avail themselves of that very reputation; and who, by crude and contemptible inferences from his doctrine of elastic undulations, and grofs mifrepresentations of his notions of an etherial fluid, have pretended to support a system of materialism; and thus have set Newton at the head of the atheistical feet, which he held in abhor-For our part, we always think with pleafure on the wonderful energy of that great mind; because it gives us a foretalte of these pleasures that await the wife and good, when the forrows flowing from the infirmities, the vices, and the arrogant vanity of man are palt;

Utque in hoc infelici campo, Ubi luctus regnat, et pavor, Mortalibus prorfus non absit solatium. Hujus enim scripta evolvas, Mentemque tantarum rerum capacem Corpori caduco superstitem credas.

It cannot be expected that, in the narrow limits prescribed to a work like ours, we can proceed to confider the various departments of this celebrated problem. We are only giving the outlines of the general doctrines of dynamics; and we have bestowed more time on those which are purely elementary than fome readers may think they deferve. We were anxious to give just conceptions of the fundamental principles of dynamics; because we know that nothing else can intitle it to the name of a demonstrative science, and because we see much indiffinctness and uncertainty, and a general vagueness or want of precision, in several elementary works which are put into the hands of persons entering on the study. This leads to errors of more consequence than a person is apt to think; because they affect our leading thoughts of mechanism itself, and our notions of the intimate nature of the visible universe.

But we must conclude the article with this great ons. problem. Many very general doctrines of dynamics remain untouched; all, namely, that relate to the rotative motion of rigid bodies, and all that relate to the mutual action of bodies on each other in the way of impulse.

The rotative motions, with the doctrine of mechanic momenta, have been considered at large in the article ROTATION of the Encycl. Britan.; and we propose to offer some important considerations on the same subject SUPPL. VOL. I. Part II.

in our fupplement to the articles MACHINE and ME. Conclusion. CHANICS. In the article Impulsion will be confidered fuch doctrines as are truly general, and independent of the specific differences of the bodies. Dynamics professes to involve no notions but those of force, and its marks and meafures.

Notwithstanding these great omissions, we must obferve that no new principle remains to be confidered. We have given all that are necessary; and there is no question that occurs in the cases omitted, which cannot be completely answered by means of the propositions already established. We have taught how to discover the existence and agency of a mechanical force, to meafure and characterife it, and then to flate what will be its various effects, according to the circumstances of

Proceeding by these principles, men have discovered Universal an universal fact, that every ACTION of one body on ano-resolution is a ther is accompanied by an equal REACTION of that o-law of the ther on the first, in the opposite direction; that is, to moterial express it in the language of dynamics, "all the phenomena which make us infer that the body A possesses a force by which it changes the motion of the body B, shew, at the same time, that B possesses a force by which it makes an equal and opposite alteration in the motion of A." This, however, is not a doctrine of abstract dynamics: it does not flow from our idea of force; therefore it was not included in our lift of the LAWS OF MOTION. It is a part of the mechanical liiftory of nature, just as the law of univerfal gravitation is; and it might be called the law of UNIVERSAL RE. ACTION. Sir Isaac Newton has, in our humble apprehension, deviated from his accustomed logical accuracy, when he admits, as a third axiom or law of motion, that reaction is always equal and contrary to action. It is a physical law, in as far as it is observed to obtain through the whole extent of the folar fystem. But Newton himself did not, in the subsequent part of his noble work, treat it as a logical axiom; that is, as a law of human thought with respect to motion: for he labours with much folicitude, and with equal fagacity, to prove, by fall and observation, that it really obtains through the whole extent of the folar fystem; and it is in this discovery that his chief claim to unequalled penetration and differnment appears.

Availing ourselves of this fact, we, with very little impulsion trouble, state all the laws of impulsion. The body A, explained for example, moving to the westward at the rate of by it; eight feet per minute, overtakes the double body B. moving at the rate of four feet per minute. What must be the consequence of their mutual impenetrability, and of the equality and contrariety of action and re-action? Their motions must be such that both sustain equal and opposite changes. They must give, in some way or other, this indication of poffessing equal and op-posite forces. This will be the case if, when the changes are completed, A and B move on in contact at the rate of four feet per minute: for here A has produced in each half of B a change of motion two; and therefore a totality of change equal to four. This is the effect, the mark, the measure, of the impulsive force of A; for it is the whole impulsion. B has produced in A a change of motion four, equal to the former, and in the opposite direction. This is the effect, mark, and measure, of the repulsive force of A; for it is the whole repulsion. And this is all that we observe in the colli-

Conclusion from of two lumps of clay; and the observation is one of the facts on which the reality of the physical law of equal action and reaction is founded: and we can make

no farther inference from this fact.

But the event might have been very different. A and B may be two magnets floating on corks on water, with their north poles fronting each other. know, by other means, that they really possess forces by which they equally repel each other. The dynamical principles already established tell us also what must happen in this case. That both conditions of equal reaction and fensible rupulsion may be fulfilled, A must come to rest, and B must move forward at the rate of four feet per minute. The fame thing must happen in the meeting of perfectly elastic bodies, such as billiard balls. If elasticities are known to be imperfect in any degree, our dynamical principles will still state the effect of their collision, in conformity to the law of equal reaction.

136 And rota. tation.

In like manner, all the motions of rotation are explained or predicted by means of the same principles of dynamics applied to the force of cohesion. This is confidered as a moving force, because, when the attraction of a magnet acts on a bit of iron attached to one end of a long lath floating on water, the whole lath is moved, although the magnet does not act on it at all: fome other force acts on it; it is its cohesion; which is therefore a moving force, and the subject of dynami-

cal discussion.

1370

138.

And thus it appears that thefe subjects do not come necessarily, nor, perhaps, with scientific propriety, under the category of dynamics, but are parts of the mechanical history of nature. Yet, did a work like ours give room in this place, the study of mechanical nature might be confiderably improved, by giving a fystem of fuch general doctrines as involve no other notions but those of force and its measures, and the hypothesis of equal reaction. Some very general, nay universal, consequences of this combination might be established, which would greatly affift the mechanician in the folution of difficult and complicated problems. Such is the proposition, that the mutual actions of bodies depend on their relative motions only, and require no knowledge of their real motions. This principle simplifies in a wonderful manner the most difficult and the most frequent eases of action which nature presents to our view; but at the fame time gives a fevere blow to human vanity, by forcing us to acknowledge that we know nothing of the real motion of any thing in the universe, and never shall know any thing of it, till our intellectual constitution, or our opportunities of observation, are completely changed.

Mr D'Alembert has made this principle still more ferviceable for extricating ourselves from the immense complication of actions that occurs in all the spontaneous phenomena of nature, by prefenting it to us in a different form, which more diffinctly expresses what may be called the elements of the actions of bodies on each other. His proposition is as follows (fee his Dy-

namique, page 73.):

"In whatever manner a number of bodies change bert's gene-their motions, if we suppose that the motion which ple of dyna each body would have in the following moment, if it were perfectly free, is decomposed into two others, one of which is the motion which it really takes in confequence of their mutual actions, the other will be fuch,

that if each body were impressed by this force alone Conclu (that is, by the force which would produce this motion) the whole fystem of bodies would be in equilibrio."

This is almost felf-evident; for if these second constituent forces be not fuch as would put the fyltem in equilibrio, the other constituent motions could not be those which the bodies really take by the mutual action,

but would be changed by the first.

For example, let there be three bodies P, Q, R, and let the forces A, B, C, act on them fuch as would give them the velocities p, q, r, in any directions whatever, producing the momenta, or quantities of motion, $P \times p$, $Q \times q$, $R \times r$, which we may call A, B, C, because they are the proper measures of the moving force. Let us moreover suppose, that, by striking each other, or by being any how connected with each other, they cannot take these motions A, B, and C, but really take the motions a, b, and c. It is plain that we may conceive the motion A impressed on the body P, to be composed of the motion a, which it really takes, and of another motion a. In like manner, B may be refolved into b, which it takes, and another β ; and C into c and x. The motions will be the same, whether we act on P with the force A, or with the two forces a and α ; whether we act on Q with the force B, or with b and β ; and on R with the force C, or with cand x. Now by the supposition, the bodies actually take the motions a, b, and c; therefore the motions α , B, and x, must be such as will not derange the motions a, b, and c; that is to fay, that if the bodies had only the motions α , β , and κ , impressed on them, they would destroy each other, and the lystem would remain at rest.

Mr D'Alembert has applied this proposition with great address and success to the very difficult questions that occur in the motions and actions of fluids, and many other most difficult problems, such as the precession of the equinoxes, &c. The cause of its utility is, that in most cases it is not difficult to find what forces will put a fystem in equilibrio; and, combining these with the known extraneous forces whose effects we are interested to discover, we obtain the motions which

really follow the mutual action of the bodies.

This is not, properly speaking, a principle: it is a form in which a general fact may be conceived. In the fame way the celebrated mathematician De la Grange observed, that a system of bodies, acting on each other in any way, is in equilibrio, if there be impressed on its parts forces in the inverse proportion of the velocities which each body takes in confequence of their action or connection; and he expresses this univerfal fact by a very simple formula; and, calling this also a principle, he solves every question with ease and neatness, by reducing it to the investigation of those velocities. In this way he has written a complete fyftem of dynamics, to which he gives the title of Mechanique Analytique, full of the most ingenious and elegant folutions of very interesting and difficult problems; and all this without drawing a line or figure, but accomplishing the whole by algebraic operations.

But this is not teaching mechanical philosophy; it is merely employing the reader in algebraic operations, each of which he perfectly understands in its quality of an algebraic or arithmetical operation, and where he may have the fullest conviction of the justness of his procedure. But all this may be (and, in the hands of an expert algebrailt, it generally is,) without any no-

nelusion. tions, distinct or indistinct, of the things, or the processes of reasoning that are represented by the symbols made use of. It is precisely like the occupation of a banker's clerk when he carries his eye up and down the columns of pounds shillings and pence, calculates the

compound interest, reversionary values, &c.

It were well if this were all, although it greatly dies of the minishes the pleasure which an accomplished mathemacholical tician might receive; but this total absence of ideas expoles even the most eminent analyst to frequent risks of paralogism and physical absurdity. Euler, who was perhaps the most expert algebraist of this century, making use of the Newtonian theorem for ascertaining the motion of a body impelled along a straight line AC (fig. 24.) by a centripetal force, by comparing it with the motion in an ellipse, of which the shorter axis was diminished till it vanished altogether, expresses his surprife at finding, that when he computes the place of the body for a time subsequent to that of its arrival at G, the body is back again, and in some place between C and A; in short, that the body comes back again to A, and plays backward and forward. He fays, that this is somewhat wonderful, and seems inconfiftent with found reason: " fed analysi magis sidendum." It must be fo. And he goes on to another pro-

In like manner Mr Maupertuis, an accomplished man, and good philosopher and geometer, finding the fymbol MVS, or the quantity of matter, multiplied by the velocity and by the distance run over during the action, always prefent itself to him as a mathematical minimum in the actions of bodies on each other; he was amused by the observation, and presumed that there was some reason for it in the nature of things. Finding that it gave him very neat folutions of many elementary problems in dynamics, he thought of trying whether it would affift him in accounting for the conflant ratio of the fines of incidence and refraction; he found that it gave an immediate and very neat folution. This problem had, before his time, occupied the minds of Des Cartes and Fermat. Each of these gentlemen folved the problem by faying, that the light did not take the shortest way from a point in the air to a point under water, but the easiest way, in conformity with the acknowledged economy of nature and confummate wifdom of its adorable Author. But how was this the easiest way, the course that economised the labour of nature? One of these gentlemen proved it to be so, if light move faster in air than in water; the other proved it to be fo, if light move faster in water than in air. Both could not be right. Manpertuis was convinced that he had discovered what it was that nature was so chary of, and grudged to waste -- it was MVS! Therefore MVS can mean nothing but labour; nothing but natural exertion, mechanical action; therefore MVS is the proper measure of action. He kept this great discovery a profound secret; and, being President of

the Royal Academy of Berlin, he proposed for the Conclusion. annual prize question, " Are the laws of motion necesfary or contingent truths?" He could not compete for the prize, by the laws of the academy; but before the time of decision, he published at Paris his differtation on the principle of the least asion; in which he pointed out the fingular fact of MVS being always a minimum; and therefore, in fact, the object of nature's economical care. He folved a number of problems by making the mini-

mum flate of $\frac{f v s}{m}$ a condition of the problems; and,

to crown the whole, shewed that the laws of motion which obtain in the universe could not be but what they are, because this economy was worthy of infinite wisdom; and therefore any other laws were impossible. The reputation of Maupertuis was already established as a good mathematician and a worthy and amiable man, and he was a favourite of Frederic. The principle of least action became a mode; and it drew attention for some time, till it went out of fashion. It is no mechanical principle, but a necessary mathematical truth, as any person must see who recollects that v is the

fame with s, and that f is the same with m v.

To avoid fuch paralog fms and fuch whims, we are Great ad convinced that it is prudent to deviate as little as pof-vantages of fible in our discussions from the geometrical method, the geometrical method, trical me-This has furely the advantage of keeping the real fub-thod. ject of discussion close in view; for motion includes the notion of lines, with all their qualities of magnitude and position. It is needless to take a representative when the original itself is in our hands, and affords a much more comprehensible object than one of its abstract qualities, mere magnitude. Let any person candidly compare the lunar theory by Mayer or Euler with that by its illustrious inventor Sir Isaac Newton, and fay which of the two is most luminous and most pleasing to the mind. No person will deny that these later personnances are incomparably more adapted to all practical purposes, and lead to corrections which it would be extremely difficult and tedious to investigate geometrically; but it must be acknowledged, at the same time, that till this be done, we have no idea whatever of the deviation of the track which this correction afcertains from the path which the moon would follow, independent of the diffurbance expressed by the correction. In like manner, Dan. Bernoulli, by mixing as much as possible the linear method with the algebraic, in his differtations on mufical chords, made the beautiful discovery of the secondary trochoids, and demonstrated the co-existence of the harmonic founds in a full musical note. Let the accomplished mathematician push forward our knowledge of dynamics by the employment of the fymbolical analysis; but let him be followed as close as possible by the geometer, that we may not be robbed of ideas, and that the student may have light to direct his steps. But, -manum e tabulâ.

DYN

DYNANOMETER, an inflrument for afcertaining neter. the relative muscular strength of men and other animals. That it would be defirable to know our relative strengths DYN

health, will hardly be denied; and there can be no Dynanodoubt but that it would be highly useful to have a meter. portable instrument by which we could ascertain the at the different periods of life, and in different states of relative strength of horses or oxen intended for the

de l' Ecole

Polytech.

nique, v .2.

Dynano- plough or the waggon. Such an instrument was invented, many years ago, by Graham, and improved by Defaguliers; but being constructed of wooden work it was too bulky to be portable, and therefore it was limited in its ufe.

M. Leroy of the Academy of Sciences at Paris con-Aructed a much more convenient Dynanometer than Graham's, confifting of a metal tube, ten or twelve inches in length, placed vertically on a foot like that of a candlestick, and containing in the inside a spiral fpring, having above it a graduated shank terminating in a globe. This shank, together with the spring, sunk into the tube in proportion to the weight acting upon it, and thus pointed in degrees the strength of the per-

fon who preffed on the ball with his hand.

This was a very simple construction, and, we think, a good one; but it did not fatisfy Buffon and Gueneau. These two philosophers wished not merely to ascertain the muscular force of a finger or a hand, but to estimate that of each limb feparately, and of all the parts of the body. They therefore employed M. Regnier to contrive a new dynanometer; and the account which he gives * of his attempts to fulfil their wishes is calculated to enliance the difficulty of the enterprize. The instrument, however, which he constructed is not fuch as appears to us to have required any uncommon skill in mechanics, or any very great stretch of thought. It confifts chiefly of an elliptical fpring twelve inches in length, rather narrow, and covered with leather that it may not hurt the fingers when compressed by the hands. This fpring is composed of the best steel well welded and tempered, and afterwards fubjected to a stronger men or animals, that it may not lofe any of its elasticity by use.

The effects of this machine are eafily explained. If a person compresses the spring with his hands, or draws it out lengthwife by pulling the two extremities in contrary directions, the fides of the fpring approach towards each other; and it has an apparatus (we do not think a very simple one) appended to it, confisting of an index and semicircular plate, by which the degree

of approach, and consequently of effort, employed, is Dyse afcertained with great accuracy. The author gives a tedious description of other appendages, by means of which horses or oxen may be employed to compress the spring. But as any mechanic may devise means for this purpose, we do not think it worth while to tranferibe that description. The English reader will find a full account of the whole apparatus in the 4th number of the very valuable miscellany entitled The Philosophical Magazine. The principle of the contrivance confifts in the elliptical fpring, of which we confess ourfelves unable to perceive the fuperiority to the spiral fpring of M. Leroy, though the author fees it very clearly

DYSENTERY (See MEDICINE-Index, Encycl.). For the cure of this difease we have the following simple prescription by Dr Perkins and Dr B. Lynde Oliver, of the State of Massachusetts in North America.

Saturate any quantity of the best vinegar with common marine falt; to one large table-spoonful of this folution add four times the quantity of boiling water; let the patient take of this preparation, as hot as it can be swallowed, one spoonful once in half a minute until the whole is drank: this for an adult. The quantity may be varied according to the age, fize, and conflitution of the patient. If necessary, repeat the dose once in fix or eight hours. Considerable evacuations I conceive (fays Dr Parkins) to be not only unnecessary, but injurious, as they serve to debilitate and prolong the difease. A tea of plantain, or some other cooling, simple drink, may be useful; and if a thirst for cyder be discovered, it may be gratified. Carefully avoid keeping this preparation effort than is likely to be ever applied to it either by in veffels partaking of the qualities of lead or copper, as the poison produced by that means may prove dan-

The fuccess of the remedy depends much on preparing and giving the dose as above directed. - The fimplicity of this treatment renders it the more valuable, as all perfons have it in their power to avail themselves of

Dr Perkins fays, that he has found it useful in agues, diarrhœas, and the yellow fever.

E A. R ARTH, in chemistry. See Chemistry-Index in this Supplement.

EARTH, in aftronomy and geography. See Ency-

EARTH, in ancient philosophy, one of the elements, the substance of which this globe is composed. To afcertain the denfity of that fubstance many experiments have been made; but perhaps none more ingenious than those of Mr Cavendish, which are detailed at full length in Part II. of the Transactions of the Royal Society of London for 1798. They were projected by the late Rev. John Michell, F. R. S. but he did not live to

AR

carry then into effect. After his death the apparatus came to the Rev. F. J. H. Wollaston, Jacksonian Professor at Cambridge, who transferred them to Mr Ca-The apparatus contrived for making fensible the attraction of small quantities of matter, and which has been improved by Mr Cavendish, is very simple: it confifts of a wooden arm 6 feet long, fufpended by the middle in an horizontal position by a slender wire 40 inches long; to each extremity is hung a leaden ball about two inches in diameter; and the whole is inclosed in a wooden case to defend it from the wind.

As no more force is required to turn this balance on

its centre than is necessary to twist the slender suspending wire, the smallest degree of attraction of a leaden weight or weights, a few (eight) inches in diameter, brought near to the finall suspended ball or balls of the balance, will be sufficient to move it sensibly aside.

To determine from hence the density of the earth, all that is necessary is, to ascertain what force is required to draw the arm aside through a given space, and

then to have recourse to calculation.

To prevent any disturbance from currents that might be produced within the box that contained the balance, by even the difference of temperature that might be occasioned by heat being communicated by the bodies of the experimenters to one fide of it more than another, it was supported in the middle of a close room; the operators, from adjoining apartments, viewed the operation through holes in the wall by means of telescopes; and the apparatus had a ftrong light thrown upon its two ends (an opening being left at each end of the box for the purpose) by means of two lamps, also in the adjoining apartments, the rays from which were likewife made to pass through the holes formed in the wall.

The two large balls were suspended from a beam near the cieling, which could be moved in an horizontal direction, by means of a ftring and pulley, fo as to be brought near to the small balls of the balance, or made to recede again, without requiring any person

to be in the room.

From this description it will be easily seen, that on the two large balls being brought near to the two small ones, but on opposite sides of each, that their forces may not counteract each other-the small suspending wire of the balance must be twisted by the movements of the arms, occasioned by attraction, which carries the fmall towards the large balls; and that the wire, endeavouring to untwift itself, will again in its turn carry the fmall balls away from the large ones. Vibrations are thus occasioned, which would continue a long time before the small balls would settle between the first point of rest and the large balls: but it is not necessary to wait for this; an ivory scale at each end of the balance enables the experimenters, by means of their telescopes, to see the two extreme divisions to which the small balls move in their vibrations, and thus to determine the middle point. The time necessary for each vibration is

A full account of these experiments, and of the calculations founded on them, would be little interesting to the great majority of our readers. We shall therefore only mention the refult. By a mean of the experiments the denfity of the earth comes out 5:48 times

greater than that of water.

By the experiments made by Dr Mafkelyne on the attraction of the hill Schehallien, the density of the earth was computed to be only 4½ times that of water. The difference of result, therefore, is almost one-fifth, which no doubt must lessen our confidence in either set of experiments, or in the principle on which they were devised.

EARTH-Worm (see Lumbricus, Encycl.) is an animal which occasions such destruction in gardens, by gnawing the tender roots of shrubs and plants, that various methods have been proposed for remedying this evil. One of the latest, and that which promises to prove the most successful, is given by M. Socoloff in

the fifth volume of the New Transactions of the Impe- Earth, rial Academy of Sciences at Petersburgh. As the de. Eaudeluce structive power of quicklime, heightened by a fixed alkali, which corrodes or diffolves all the tender parts of animals, has been long known, it occurred to our author that this mixture would be the best means for accomplishing the object which he had in view. He therefore took three parts of quick-lime, newly made, and two parts of a faturated folution of fixed alkali in water, and thence obtained a fomewhat milky liquor fufficiently caustic, highly hostile and poisonous to earthworms and other small animals; for as soon as it touched any part of their bodies, it occasioned in them violent fymptoms of great uneafinefs. If this liquor be poured into those holes in which the earth-worms reside under ground, they immediately throw themselves out as if driven by fome force; and, after various contorfions, either languish or die. If the leaves of plants or fruit-trees, frequented by the voracious caterpillars, which are so destructive to them, be sprinkled over with this liquor, these insects suddenly contract their bodies and drop to the ground. For though Nature has defended them tolerably well by their hairy skins from any thing that might injure their delicate bodies, yet as soon as they touch with their feet or mouths leaves which have been moistened by this liquor, they become as if it were stupisied, instantly contract themselves, and

With regard to plants or corn, these sustain no injury from the liquor, because it has no power over the productions of the vegetable kingdom, as our author has fully learned from experience; or if any hurt is to be suspected, all the danger will be removed by the first shower that falls. This liquor may be procured in abundance in every place where lime is burnt. If the lime be fresh, one part of it infused into about seventy parts of common water will produce real lime water. The want of the fixed alkali may be supplied by boiling wood-ashes in water, and thickening the ley by evaporation.

This liquor might be employed also to kill bugs and other domestic infects; but on account of its strong lixivious fmell, M. Socoloff thinks it could not be used with fafety in houses that are inhabited. Nothing, however, more speedily or more effectually destroys bugs, as our author fays he has repeatedly experienced, than the oily pickle that remains in cashs in which falt-

ed herrings have been packed.

EAU DE LUCE, a fragrant alkaline liquor which was some years ago in great repute, especially among the fair fex, and of which the leading perfection is, that

it shall possess and retain a milky opacity.

Mr Nicolfon, in the fecond number of his valuable journal, tells us, that being informed by a philosophical friend, that the usual recipes for making this compound (fee CHEMISTRY, Encycl. no 1037.) do not succeed, and that the use of maltic in it has hitherto been kept a fecret, he made the following trials to procure a good eau de luce.

One dram of the rectified oil of amber was diffolved in four ounces of the strongest ardent spirit of the shops; its specific gravity being .840 at 60 degrees of Fahrenheit. A portion of the clear spirit was poured upon a larger quantity of fine powdered mastic than it was judged could be taken up. This was occasionally 550

was for the most part gradually disfolved. One part of the oily folution was poured into a phial, and to this was added one part of the folution of massic. No opacity or other change appeared. Four parts of strong caustic volatile alkali were then poured in, and immediately shaken. The fluid was of a dense opake white colour, affording a flight ruddy tinge when the light was feen through a thin portion of it. In a fecond mixture, four parts of the alkali were added to one of the folution of massic; it appeared of a less dense and more yellowish white than the former mixture. More of the gum refinous folution was then poured in; but it fill appeared less opake than that mixture. It was ruddy by transmitted light. The last experiment was repeated with the oily folution instead of that of mastic. The white was much less dense than either of the soregoing compounds, and the requilite opacity was not given by augmenting the dofe of the oily folution. No ruddiness nor other remarkable appearance was seen by transmitted light. These mixtures were left at repose for two days; no separation appeared in either of the compounds containing mastic; the compound consisting of the oily folution and alkali became paler by the feparation of a cream at the top.

It appears, therefore, that the first of these three mixtures, subject to variation of the quantity of its ingredients, and the odorant additions which may be

made, is a good eau de luce.

In a subsequent number of the same Journal, we have the following recipe by one of the author's correspondents, who had often proved its value by experience. " Digest ten or twelve grains of thewhitest pieces of maflic, selected for this purpose and powdered, in two ounces of alcohol; and, when nearly diffolved, add twenty grains of elemi (See Amyris, Encycl.). When both the refins are dissolved, add ten or fifteen drops of rectified oil of amber, and fifteen or twenty of effence of bergamot: shake the whole well together, and let the fæces subside. The folution will be of a pale amber colour. It is to be added in very small portions to the best aqua ammoniæ puræ, until it assumes a milky whitenels, shaking the phial well after each addition, as directed by Macquer. The strength and causticity of the ammoniac are of most effential consequence. If, upon the addition of the first drop or two of the tincture, a dense opake coagulated precipitate is formed, not much unlike that which appears on dropping a folution of filver into water flightly impregnated with common falt, it is too ftrong, and must be diluted with alcohol. A considerable proportion of the tincture, perhaps one to four, ought to be requifite to give the liquor the proper degree of opacity."

EAVES-BOARD, or EAVES-LATH, a thick featheredged board, usually nailed round the eaves of a house for the lowermost tiles, slate, or shingles, to rest upon.

ECLIPSAREON, an instrument invented by Mr Ferguson for shewing the phenomena of eclipses; as

their time, quantity, duration, progress, &c.

ECLIPTIC. See Encycl. both under ECLIPTIC and in Astronomy-Index. It was observed in As-TRONOMY, Encycl. nº 407. that the obliquity of the ecliptic has been found gradually to decrease. This was observed, among others, by La Lande, who, in the third edition of his aftronomy, reckoned the fecular di-

Bau de luce agitated without heat; by which means the gum refin minution of this obliquity at 50 feconds. From a new Ecliptic examination, however, of anrient observations, he has Edyston fince found reason to estimate it at only 36 seconds; but whether this be perfectly accurate, is very doubtful. The mean obliquity was determined for the 1st of January 1793, with circular instruments, by Mechain at Barcelona, and Piazzi at Palermo, to be 23° 27' 53".3. Yet the observation of the summer solftice of 1796, by Mechain and Le Français, gave 11 feconds more; which was justly considered as a perplexing circumstance. But, as one of the ablest of our literary journalists observes, might not this difference arise from the uncertainty of our tables of refraction, as affected by the hygroscopic variations of the atmosphere?

ECLIPTIC Bounds, or Limits, are the greatest distances from the nodes at which the fun or moon can be eclipfed, namely, near 18 degrees for the fun, and 12 de-

grees for the moon.

EDYSTONE ROCKS, fo remarkable for the lighthouse built on them, obtained their name from the great variety of contrary fets of the tide or current in their vicinity. They are fituated nearly S S. W. from the middle of Plymouth Sound, according to the true meridian. The distance from the port of Plymouth is nearly 14 miles, and from the promontory called Rambead about 10 miles. They are almost in the line, but Smeaton fomewhat within it, which joins the Start and the Li-Account zard points; and as they lie nearly in the direction of the Edy vessels coasting up and down the channel, they were Light-be necessarily, before the establishment of a light house, very dangerous, and often fatal to ships under such circumstances. Their situation, likewise, with regard to the Bay of Bifcay and Atlantic ocean, is fuch, that they lie open to the swells of the Bay and ocean from all the fouth-western points of the compass: which fwells are generally allowed by mariners to be very great and heavy in those seas, and particularly in the Bay of Biscay. It is to be observed, that the soundings of the sea from the south westward toward the Edystone are from 80 fathoms to 40, and everywhere till you come near the Edystone the sea is full 30 fathoms in depth; so that all the heavy seas from the fouthwest come uncontrouled upon the Edystone rocks, and break on them with the utmost fury.

The force and height of these seas is increased by the circumstance of the rocks stretching across the Channel, in a north and fouth direction, to the length of above 100 fathoms, and by their lying in a soping manner toward the fouth-west quarter. This sliving of the rocks, as it is technically called, does not crase at low water, but still goes on progressively; so that, at 50 fathoms westward, there are 12 fathoms water; nor do they terminate altogether at the distance of a mile. From this configuration it happens, that the feas are fwelled to fuch a degree in florms and hard gales of wind, as to break on the rocks with the utmost violence.

The effect of this slope is likewife fentibly felt in moderate, and even in calm weather; for the libration of the water, caused in the Bay of Biseay in hard gales at fouth-west, continues in those deep waters for many days, though fucceeded by a calm; infomuch, that when the fea is to all appearance finooth and even, and its furface unruffled by the flightest breeze, yet those librations still continuing, which are called the groundfwell, and meeting the flope of the rocks, the fea breaks I stone upon them in a frightful manner, so as not only to obstruct any work being done on the rock, but even the landing upon it, when, figuratively speaking, you might go to sea in a walnut shell. A circumstance which still farther increases the difficulty of working on the rock is, there being a sudden drop of the surface of the rock, forming a step of about four and a half, or five feet high; fo that the feas, which in moderate weather come fwelling to this part, meet fo fudden a check that they frequently fly to the height of 30 or 40 feet.

Notwithstanding these difficulties, it is not surprising that the dangers to which navigators were exposed by the Edystone rocks should make a commercial nation defirous of having a light-house on them. The wonder is, that any one should be found hardy enough to undertake the building. Such a man was first found in the person of Henry Winstanley of Littlebury in Effex, Gent. who, in the year 1696, was furnished by the master, wardens, and assistants, of the Trinity-house of Deptford Strond with the necessary powers to carry

the defign into execution.

Mr Winstanley had distinguished himself in a certain branch of mechanics, the tendency of which is to raife wonder and furprife. He had at his house at Littlebury a fet of contrivances, fuch as the following: Being taken into one particular room of his house, and there observing an old slipper carelessly lying on the floor; if, as was natural, you gave it a kick with your foot, up flarted a ghost before you. If you fat down in a certain chair, a couple of arms would immediately clasp you in, so as to render it impossible to disentangle yourfelf till your attendant set you at liberty. And if you fat down in a certain arbour by the fide of a canal, you were forthwith fent out affoat to the middle of the canal, from whence it was impossible for you to escape till the manager returned you to your former place. -Whether those things were shewn to strangers at his house for money, or were done by way of amusement to those that came to visit the place, is uncertain, as Mr Winstanley is said to have been a man of some property; but it is at least certain, that he established a place of public exhibition at Hyde Park corner, called Winstanley's water-works, which were shewn at stated times at one shilling each person. The particulars of those water-works are not now known; but, according to the tafte of the times, we must naturally suppose a great variety of jets d'eau, &c.

These particulars are at present of no other importance than that they ferve to give a sketch of the talents and turn of mind of the original undertaker, and to account for the whimfical kind of buildings which he erected on the Edystone; from the design of which, it feems as if it were not fufficient for his enterprifing genius to erect a building on the fpot, where, of all others, it was least likely to stand unhurt; but that he would also give it an elevation, in appearance the most liable to subject it to damage from the violence of the wind

and waves.

This ingenious man entered upon his great undertaking in 1696, and completed it in fomething more than four years. The first summer was occupied with ma king 12 holes in the rock, and in fastening 12 great irons, which were to hold the work that was afterward to be done. The next fummer was fpent in making a folid body, or round pillar, 12 feet high and 14 feet in diameter. In the third year, the aforefaid pillar or Edystone work was make good at the foundation, from the rock, to 16 feet in diameter; and all the work was raised, which, to the vane, was 80 feet high. Being all finished, with the lantern, and all the rooms that were in it; we "ventured (fays Mr Winstanley) to lodge there foon after midfummer, for the greater dispatch of this work: but the first night the weather came bad, and fo continued, that it was eleven days before any boats could come near us again; and not being acquainted with the height of the feas rifing, we were almost all the time drowned with wet, and our provisions in as bad a condition, though we worked night and day, as much as possible, to make shelter for ourselves."

Mr Winstanley, however, fucceeded in fetting up the light on the 14th of November in that year (1698); but he was detained till within three days of Christmas before he could return to shore, being almost at the last

extremity for want of provisions.

In the fourth year, observing the effects that the sea produced on the house, burying the lantern at times, although more than 60 feet high, Mr Winstanley encompassed the aforesaid building early in the spring with a new work of four feet thickness from the foundation, making all folid for near 20 feet high; and taking down the upper part of the first building, and enlarging every part in its proportion, he raifed it 40 feet higher than it was at first: Yet, he observes, "the fea, in times of storms, slies in appearance one hundred feet above the vane, and at times doth cover half the fide of the house and the lantern as if it were under water."

No material occurrences concerning this building happened till November 1703, when the fabric, needing fome repairs, Mr Winstanley went down to Plymouth to superintend the work. And "we must not wonder (fays Mr Smeaton), if, from the preceding accounts of the violence of the feas, and the ftructure of the lighthouse, the common fense of the public led them to suppofe this building would not be of long duration. The following is an anecdote which I received to the same effect from fo many persons that I can have no doubt of the truth of it: Mr Winstanley being among his friends previous to his going off with his workmen on account of those reparations, the danger being intimated to him, and that one day or other the light-house would certainly be overfet; he replied, " He was fo very well affured of the ftrength of his building, he should only wish to be there in the greatest storm that ever blew under the face of the heavens, that he might fee what effect it would have on the structure "-It happened that Mr Winstanley was but too amply gratified in this wish; for while he was there with his workmen and light-keepers, that dreadful form began, which raged most violently on the 26th of November 1703, in the night; and of all the accounts of the kind which history furnishes us with, we have none that has exceeded this in Great Britain, or was more injurious or extensive in its devastation. The next morning, November 27th, when the violence of the storm was fo much abated that it could be feen whether the lighthouse had suffered by it, nothing appeared standing, but, upon a nearer inspection, some of the large irons by which the work was fixed upon the rock; nor were any of the people, or any of the materials of the building, ever found afterwards, fave only part of an iron

Edystone chain, which had got so fast jambed into a chink of the rock, that it could never efterwards be difengaged

till it was cut out in the year 1756."

Thus perished Mr Winstanley, together with his building: but so great was the utility of that building while it stood, that the public could not fail to be defirous of having another in its place. Accordingly, in 1706, an act of parliament of the 4th of Queen Anne was passed, for the better enabling the master, &c. of the Trinity house of Deptford-strond to rebuild the fame. By this act, the duties payable by shipping pasfing the light house were vested in the corporation of the Trinity house, who were empowered to grant a lease to such undertaker or undertakers as they should approve. In consequence, they agreed with a Captain Lovel or Lovet for a term of 99 years, commencing from the day on which a light should be exhibited, and continuing fo long as that exhibition should last during the faid term. On this foundation Captain Lovet engaged Mr John Rudyerd to be his engineer or architect and surveyor.

It does not appear that Mr Rudyerd was bred to any mechanical bufiness or scientific profession, being at that time a filk mercer on Ludgate hill; nor is it known that, in any other instance, he had distinguished himself by any mechanical performance before or after. His want of personal experience, however, was in a degree affilted by Mr Smith and Mr Norcutt, both shipwrights in

the king's yard at Woolwich.

It is not, as Mr Smeaton observes, very material in what way this gentleman became qualified for the execution of his work; it is sufficient that he directed the performance in a mafterly manner, and fo as perfectly to answer the end for which it was intended. He saw the errors in the former building, and avoided them; instead of a polygon he chose a circle for the outline of his building, and carried up the elevation in that form. His principal aim appears to have been use and simplicity; and indeed, in a building so situated, the former could hardly be acquired in its full extent without the latter. He seems to have adopted ideas the very reverse of his predecessor; for all the unwieldy ornaments at top, the open gallery, the projecting cranes, and other contrivances, more for ornament and pleafure than use, Mr Rudyerd laid totally aside. He saw, that how beautiful foever ornaments might be in themselves, yet when they are improperly applied and out of place, by affecting to shew a taste, they betray ignorance of its first principle, judgment; for whatever deviates from propriety is erroneous, and at best insipid.

It is impossible for us to give an accurate account of the construction of Mr Rudyerd's light house. We can only fay, in general terms, that it was altogether built of wood; for the courses of moorstone, which Mr Rudyerd, adverting to the maxim, that weight is best refifted by weight, introduced into the folid part of his building, must be considered as being of the nature of ballast; the weight of these amounted to above 270 tons. The main column of the building confifted of one simple figure, being an elegant fruitum of a cone, unbroken by any projecting ornament, or any thing on which the violence of the ftorms could lay hold; meafuring, exclusively of its sloping foundation, 22 feet and eight inches on its largest circular base; 61 feet high above that circular base; and 14 feet and three inches in

diameter at the top: fo that the circular base was some. Edysto what greater than one-third of the total height, and the diameter at the top was less than two-thirds of the base at the greatest circle. On the flat roof of this main column, as a platform, Mr Rudyerd fixed his lantern, which was an octagon of ten feet and fix inches diameter externally. The mean height of the windowframes of the lantern above the balcony floor was nearly nine feet; so that the elevation of the centre of the light above the highest side of the base was 70 feet; that is, lower than the centre of Mr Winstanley's second lantern by feven feet, but higher than that of his first by 24 feet. The width of Mr Rudyerd's lantern was, however, nearly the same as that of Mr Winstanley's fecond: but inflead of the towering ornaments of iron. work, and a vane that rose above the top of the cupola no less than 21 feet, Mr Rudyerd judiciously contented himself with finishing his building with a round ball of two feet and three inches diameter, which terminated at three feet above the top of his cupola. The whole height of Mr Rudyerd's light-house, from the lowest side to the top of the ball, was 92 feet, on a base of 23 feet and four inches, taken at a medium between the highest and lowest part of the rock that it covered. The whole building was completed in the year 1709, three years from its commencement.

This great work, after having braved the elements for forty-fix years, was burnt to the ground in 1755. On the 2d of December of that year, when the lightkeeper, then on the watch, went, about two o'clock in the morning, into the lantern, to fnuff the candles according to custom, he found it in a smoke; and in spite of all that he and his companions could do, the whole edifice was on fire in the compass of little more than eight hours, and in a few days was burnt to its foundation. The three light-men were with much difficulty got on shore, when one of them immediately ran off, and has never fince been heard of. Another, who had been dreadfully burned by melted lead, of which, according to his own account, he had fwallowed a quantity, lingered in agony for twelve days, and then expired. His stomach being opened, there was found in it a folid piece of lead of a flat oval form, which weighed feven ounces and five drachms; and thus was verified an affertion which, to the furgeon and others who attended him, appeared altogether incredible, viz. that any human being could live after receiving melted lead

into the stomach.

On the destruction of Mr Rudyerd's light house, Mr Smeaton (fee SMEATON in this Supplement) was recommended by Lord Macclesfield, then prefident of the Royal Society, as the fittest person in England to build another. It was with fome difficulty that he was able to perfuade the proprietors that a stone building, properly confiructed, would in all respects be preferable to one of wood; but having at last convinced them, he turned his thoughts to the shape which was most suitable to a building fo critically fituated. Reflecting on the structure of the former buildings, it feemed a material improvement to procure, if possible, an enlargement of the base, without increasing the fize of the weist, or that part of the building which is between the top of the rock and the top of the folid work. Hence he thought a greater degree of strength and stiffness would be gained, accompanied with less refistance to the acting

More, power. On this occasion, the natural figure of the waith or bole of a large spreading oak occurred to Mr Smeaton.

" Let us (fays he) confider its particular figure.— Connected with its roots, which lie hid below ground, it rifes from the furface with a large fwelling bafe, which at the height of one diameter is generally reduced by an elegant curve, concave to the eye, to a diameter less by at least one third, and sometimes to half its original base. From thence, its taper diminishing more flowly, its fides by degrees come into a perpendicular, and for some height form a cylinder. After that, a preparation of more circumference becomes neceffary, for the ftrong infertion and establishment of the principal boughs, which produces a fwelling of its diameter.-Now we can hardly doubt but that every fection of the tree is nearly of an equal strength in proportion to what it has to refiff; and were we to lop off its principal boughs, and expose it in that state to a rapid current of water, we should find it as capable of refifting the action of the heavier fluid, when divested of the greater part of its clothing, as it was that of the lighter, when all its spreading ordaments were exposed to the sury of the wind: and hence we may derive an idea of what the proper shape of a column of the greatest stability ought to be, to refist the action of external violence, when the quantity of matter is given

of which it is to be composed."

The next thing to be confidered was, how the blocks of sone could be bonded to the rock, and to one another, in fo firm a manner as that not only the whole together, but every individual piece, when connected with what preceded, should be proof against the greatest violence of the fea. For this purpose, cramping was the first idea, but was rejected on account of the great quentity of iron which was necessary, and from the trouble and loss of time which would attend that operation. In its place was fubflituted the method of devetailing. From fome specimens which Mr Smeaton had feen in Belidor's description of the stone floor of tle great sluice at Cherburgh, (where the tails of the upright headers are cut into dovetails for their infertion into the mais of rough mafonry below,) he was led to think, that if the blocks themselves were, both inside and outfide, formed into large dovetails, they might be managed fo as to lock one another together, being primarily engrafted into the rock; and in the round or entire courses above the top of the rock, they might all proceed from, and be locked to, one large centre itone. Thefe particulars being digested in his own mind, he explained his defign by the help of drawings; with which, after mature deliberation, the proprietors were perfectly fatisfied; and declared, that the scheme was not only in itself practicable, but, as appeared to them, the only means of doing the business effectually.

During this time Mr Smeaton had never visited the rock on which he was to be employed: he therefore refolved to go to Plymouth early in the spring of 1756, that he might lose no opportunity of viewing it. At Plymouth he met Mr Josias Jessop, to whom he was referred for information and assistance, and who afterwards proved of great service: he was not only an approved workman in his branch as a shipwright, but a competent draughtsman and an excellent modeller; 'in which last (fays the author) he was accurate to a great

SUPPL. VOL. I. Part II.

degree: he therefore appeared to be a very fit person Edystone. to overlook the exact execution of a delign given.' Mr Jessop, like others, expressed his doubts that a stone building could stand on the Edystone: but they were removed by the proposed mode of its construction.— As Mr Smeaton was impatient to go to the rock, he feized the first opportunity that seemed to promise any chance of landing on it. On the 2d of April he got within a stone's throw of it, but could not land: on the 5th he was more fortunate; he now landed, and flaid on the rock for two hours and a half. This time was employed in taking a general view of the whole. No remains of the house could be perceived either on the rock, or about it, except the greatest part of the iron branches that had been fixed by Mr Rudyerd; and fome of the moorstones were discerned lying in the bottom of the gut. Such traces were also observed of the fituation of the irons fixed by Mr Winstanley, as to render it no very difficult talk to make out his plan, and the polition of the edifice: whence it appeared very probable, that Mr Winstanley's building was overfet altogether, and that it had torn up a portion of the rock itself, as far as the irons had been fastened in it. With regard to the sleps, which were faid to have been cut in the rock by Mr Rudyerd, the traces of only five were remaining; these were faintly cut, and without much regularity. It was next tried in what degree the rock was workable; and Mr Smeaton had the fatisfaction of finding every thing fucceed to his wishes.

Having thus determined that there was no impracticability in fixing a stone building, it became of the greatest importance to secure a more safe and certain landing on the rock; as it would frequently happen, while the vessels were lying off the rock, waiting for a favourable time to enter the gut, that tides might change, ground swells come on, winds shift, and storms arise, which would of course make it desirable to return to Plymonth, if possible, though the purpose of the voyage was unperformed. In addition to this, when veffels had got with some facility into the gut, they frequently could not get out again without extreme danger: for as the larger fort had not room to turn in it, they were in reality obliged to go out stein forward; the Sngar loaf rock being fo critically placed, with shallow water on both sides of it, that it prohibits a thorough passage. It was true, indeed, that by the skill and expertness of those seamen who had frequently attended the fervice of the Edystone, not only row boats, but the attendant veffels, after having delivered their cargoes, had been carried quite through, at the top of an high tide, with a fair wind and fmooth water: but this was not an experiment to be commonly repeated. The two voyages which Mr Smeaton had made were in a small failing vessel of about ten or twelve tons burthen, which was built for the fervice, and called the Edystone Boat. It occurred to him, that while the light house was standing, if the boat had been staved on the rocks while lying in the gut, there was a possibility of the men being faved by getting into the house, as the light-keepers would have been ready to throw out a rope to their affishance: but that if any accident of the kind were to happen now that the house was down, and no protection nor shelter to be had, there was little chance of their escape; - and these considerations being

4 A

Edystone. likely to cast a damp on every exertion to land, he determined to go out no more without another failing boat to attend.

The weather being unfavourable for vifiting the rock, all exertions were used to forward the work on shore; and, first, a work-yard was chosen in a field adjacent to Mill Bay, about a mile west from Plymouth. The next object was to procure moor-stone, or granite; and with this view the author visited Hingstone Downs, and observed the manner of working the stone, which He next went to Lanlivery, near Fowey harbour, from which place the stone work for the late

light-house had been furnished

During this time he had made five voyages to the rock with little fuccess: the event of the last had strongly pointed out, that the much greater tonnage of the stone which must be necessary to be carried out and fixed, in case of a stone building, than was requisite in the compositions of his predecessors, would make the uncertainty and delay which they had described as being attendant on their voyages, in order to fix their work, bear far heavier on the scheme; and would thus occasion the whole time of the performance to be lengthened. It appeared, therefore, that had a veffel been fixed within a quarter of a mile, or some such competent distance from the rocks, and which should be capable of lodging the workmen, all their tools and loofe materials, the feveral pieces of wrought stone only excepted, that then the workmen might, by means of small row-boats or yawls, have effected a landing both of themfelves and of their materials, and have been at work on the rock during the greatest part of those days which otherwise, as voyagers, they would have lost in fruitless endeavours to get to the place of action. Agreeably to this opinion, it was proposed to build a strong and very well found floop of about fifty tons, with iron chains for mooring her on the rocky ground near the Edystone. A vessel was in fact afterward moored in this situation: but it was one not built for the service, but originally intended to have been stationed as a temporary floating light during the rebuilding of the light-house.

Mr Smeaton now made a fixth voyage to the rock, on which he employed himself for nineteen hours in taking fuch dimensions as would enable him to make an accurate model of its surface. He likewise attempted a feventh voyage: but being unable to reach the Edyflone, he bore away for Falmouth, in order to examine the moor-stone works at Constantine in that neighbourhood. From the difficulties which occurred here, as well as at other places, he was convinced that a sufficient quantity of moor-stone could not be readily and expeditiously procured, in order to complete the whole building; and that he must therefore confine the moorstone to the outside, as being more durable, and content himself with the use of Portland, or some other free-working stone, for the inside work. In consequence, after making three more voyages to the rock, and completing all the observations which he was defirous of taking there, he vifited the isle of Portland in his return to London, and made the necessary agreements

for carrying on his work.

On his arrival in London, Mr Smeaton again met the proprietors, from whom he experienced the greatest liberality and confidence: they declared, that as he was

now apprized of what was to be done, they left both Edystone the time and the means of its accomplishment to him.

On this occasion (he observes), I found myself totally unfettered; and perhaps no resolution of the proprietors ever more conduced to the ultimate success of the work than this, which fet me fo much at liberty. Had they been of the same temper and disposition of by far the greatest part of those who have employed me, both before and fince, their language would have been, Get on, Get on, for God's sake. get on! the public is in expectation; get us fomething speedily to shew, by which we may gain credit with the public! -This, however, was not their tone, which I looked upon as a happy earnest from the proprietors in the outset.'

During his stay in London, he resolved, as an absolutely necessary preliminary step, to form models of the rock, both in its present state and as cut to the intended shape for receiving the building. Connected with the last was a model of the building itself, shewing distinctly how the work was to be adapted to each feparate step in the ascent of the rock, and particularly exhibiting the construction of the first entire course after rifing to the level of the upper furface of the rock: to this a folid being fitted, the model shewed the external form of the whole building, including the lantern; while, by a fection on paper, the whole infide work was represented. These models, as well, indeed, as most of the material parts of the business, were the entire work of Mr Smeaton's own hands. After exhibiting these to the Lords of the Admiralty, who expressed their warmest approbation, he returned to Plymouth on

the 23d of July 1756.

On his arrival at Plymouth, he found that Mr Jessop had completely fitted up, for prefent fervice, the floop, which had before been used as an attendant; as well as the Edystone boat, and a large yawl, with fails and oars. Another seaman was now taken into the service, which made the number of the crew fix. The Neptune Buss, which had been built for the purpose of exhibiting a temporary light, but which was afterward moored near to the rock, was arrived: but as her deflination was not known, all orders for mooring-chains were fuspended, and Mr Smeaton was obliged to content himself with preparing cables in the best manner that he could for mooring the floop in that fituation. As the weather was unfavourable, he had but one opportunity of visiting the rock; he therefore applied vigoroufly to prepare every thing on shore. bufiness was to establish the working companies, which were to confift of two complete fets of hands, to relieve each other by turns; fo that, whenever winds and tides would permit, the work might be purfued by day and night. In his distribution and management of these people he appears to have acted with great judgment. He made choice of, and agreed with, Mr Thomas Richardson, a master mason of Plymouth, to act as foreman of one of the companies; and also with William Hill, who had been some time foreman to another master mason of the same place, to act as the other foreman. He likewise entered three masons, and nine tinners (Cornish miners), as a company, to go out with Mr Richardson to take the first turn, or week, commencing from Saturday the 31st of July. Mr Jessop was appointed general affiftant. The wages of the foremen, while at fea, were to be 58. per day certain; some and for every hour spent on the rock, the farther preminm of 1s. - but when employed in the work-yard or otherwise on shore, their wages were to be 3s. 6d. per day. The wages of the masons were to be 28 6d per day certain at fea, with a premium of 9d. per hour; and the tinners were to have 2s. per day certain at fea, and 8d. per hour. In the work-yard, or at shore, the masons were to have 20d. and the tinners 18d. per day, and to be paid for over-time when required to work; -and that the seamen might not want inducement to do their utmost in landing the workmen at the Edystone as early as posible at every opportunity, and in fupplying them with what was necessary for keeping them at work, over and above their weekly wages, which were fettled at 8s. per week, they were all to receive a premium for every landing on the rock; the master seamen having 2s. 6d. and the ordinary men 2s. to make their advantage equivalent to that of the other workmen, in whatever fervice the feamen, who were constantly on duty, were employed. Mr Jessop, as general assistant, was to have 10s. 6d. per day at sea, and 58. per day on land; and every one was to supply himfelf with victuals .- Mr Smeaton likewife agreed for half an acre of ground on the west side of Mill-bay for a work-yard, as before mentioned, which he marked out, and ordered to be fenced with boards. At this time arrived Mr John Harrison, who was to act as clerk to the Edystone works, with whom a plan was digested for keeping the accounts and correspondence; and for the distinct noting of so great a variety of articles, it was found expedient to open fourteen different

Matters being thus fettled on shore, and the weather having become more promising, Mr Richardson and his company embarked in the floop, with her ground tackle on board, attended by the author and Mr Jeffop, and having also the yawl properly manned. Having landed on the rock, Mr Smeaton proceeded to fix the centre, and to lay down the lines of the intended work on its surface; and being followed by Mr Richardson, he, with sharp picks, left indelible traces of those lines, fo as that the workmen might proceed on them when ever they should be able to land. The roughness of the sea, however, soon rendered it advisable to return to the floop; and from the fame cause it was thought unfafe to attempt to moor her that evening. On the next day, the wind continued to blow very fresh: but on the following they were able to moor the floop; and every one being anxious to make a beginning, the whole company landed on the rock, and immediately began the work, which was purfued for about four hours, when they were driven off by the sea. On the following day, all hands landed before fun-rife, and worked, during that tide, for fix hours; and in the afternoon's tide they again landed, and continued the work, by the help of links, till ten o'clock at night. They purfued this course for some time with very little interruption, working, at an average, for about five hours in each tide.

The weather had now been fair from August 27th to the 14th of September; and in this space they had worked for 177 hours on the rock. During this interval, also, Mr Jessop had prevented a West Indiaman homeward bound, and a man of war's tender, from driving on the rocks, to which they were approaching,

though they themselves were not aware of it. On the Edykone. 16th, the work on the rock was in the following fituation: 'The lowest new step (the most difficult to work, because the lowest,), with its dovetails, was quite completed.—The fecond step was rough bedded, and all its dovetails scapelled ont.—The third step (being the lowest in Mr Rudyerd's work) was smooth bedded, and all the dovetails roughed out.—The fourth was in the like state. The fifth was rough bedded, and its dovetails were fcapelled out; and the fixth was fmooth bedded, and all the dovetails roughed out .- Lastly, the top of the rock, the greatest part of the bulk whereof had been previously taken down as low as it could be done with propriety, was now to be reduced to a level with the upper furface of the fixth step; the top of that step being necessarily to form a part of the bed for the feventh or first regular course: so that what now remained, was to bring the top of the rock to a regular floor by picks; and from what now appeared (as all the upper parts that had been damaged by the fire were cut off) the new building was likely to rest on a batis even more folid than the former lighthouses had done.

The equinoctial winds that were now reigning, afforded little prospect of doing much more work on the rock for this feafon: for though a more moderate interval of weather might be expected, yet that must be employed in weighing the Buss's moorings. To prevent the necessity of this, however, it was an object of confideration, whether they could not dispense with that operation, and thereby have a little more time for work on the rock. Mr Smeaton's contrivance for this purpose was admirable; but it was rendered vain by the bad failing of the bufs. After overcoming many difficulties, the buss with Mr Smeaton on board was driven at a great rate towards the bay of Bifcay, in danger every hour of being swallowed up by the waves, or dashed in pieces on the rocks of Scilly. At last, on Friday morning the 26th of November, they reached Plymouth Sound, and relinquished all thoughts of return-

ing to their work on the rock that feafon.

The winter therefore of 1756, and the following fpring, were employed in preparing materials for the outwork: the masonry particularly required great attention. It was a desirable object to use large and heavy pieces of stone in the building; yet their fize must necessarily be limited by the practicability of landing them with fafety. Now fmall veffels only could deliver their cargoes alongside of this hazardous rock; and these could not deliver very large stones, because the fudden rifing and falling of the veffels in the gut amounted frequently to the difference of three or four feet, even in moderate weather; fo that in case after a ftone was raifed from the floor of the veffel, her gunwale should take a swing, so as to hitch under the stone, one of a very large magnitude must, on the velfel's rifing, infallibly fink her. From this confideration, it was determined that fuch stones should be used as did not much exceed a ton weight; though occasionally particular pieces might amount to two tons. That they might attain a certainty in putting the work together on the rock, the stones of each course were tried together in their real fituation with respect to each other; and they were so exactly marked, that every stone, after the course was taken asunder, could be replaced in the identical position in which it lay on the

4 A 2

platform,

this judged fufficient; for every course was not only tried fingly together on the platform and marked, but the course above it was put on it, and marked in the fame way; fo that every two contiguous courfes might fit each other on the outfide, and prevent an irregularity in the outline. This degree of accuracy might feem fuperfluous: but as the nature of the building required the workmen to be in a condition to refift a storm at every step, it became necessary to fix the centre stone first, as being least exposed to the stroke of the sea; and in order to have fure means of attaching all the rest to this, and to one another, it was indispensable that the whole of the two courses should be tried together; in order that, if any defect appeared at the outfide, by an accumulation of errors from the centre,

it might be rectified on the platform.

Another circumstance, to which Mr Smeaton was particularly attentive, and concerning which his remarks are very valuable, was to afcertain the most proper composition for water cements. In making mortar for buildings exposed to water, tarras had been most esteemed: but still there were objections to its use. Mr Smeaton was therefore induced to try the terra puzzolana, found in Italy, as a substitute for tarras. Fortunately there was a quantity of it in the hands of a merchant at Plymouth, which had been imported as a venture from Civita Vecchia, when Westminster-bridge was building; and which he expected to have fold for that work to a good advantage, but failed in his speculation; for having found that tarras answered their purpole, neither commissioners, engineers, nor contractors, would trouble themselves to make a trial of the other material. This was found in every respect equal to tarras, as far as concerned the hardening of watermortar, if not preferable to it; and if made into a mortar with lime produced from a stone found at Aberhardness, any of the compositions commonly used in dry perior to any which Mr Smcaton had feen, infomuch, that he did not doubt its making a cement that would and durability.

These preliminary arrangements being settled, they proceeded, on the 3d of June 1757, to carry out the Neptune buss, and to begin the work. After getting up the moorings (a work of no small difficulty and some danger), and after fixing the fender-piles, the shears, windlass, &c. the first stone was landed, got to its place, and fixed, on Sunday the 12th of June; and on the next day the first course was completed. On the 14th, the fecond course was begun: but, in consequence of a fresh gale, the workmen were obliged to quit the rock, after fecuring every thing as well as possible. Such was the violence of the gale, that it was impracticable for the boats to get out of the gut, otherwise than by pasfing the Sugar-loaf rock, in which they providentially fucceeded. On the 18th, they were again as fuddenly driven from their work, and several pieces of stone were washed away by the violence of the sea. In the night of the 6th of July, the watch on the deck of the buss espied a fail on the rocks, and one of the yawls was fent to her relief, which brought back the whole crew,

Edystone. platform, within the fortieth part of an inch :- nor was It was a fnow of about 130 tons burthen, which was Edyston returning in ballast from Dartmouth; but not knowing exactly where they were, they had mistaken the rocks for fo many fishing boats, till it was too late to clear them; and on the veffel's striking, she filled so quickly, that the boat floated on deck before they could get into it.

> During this time, the building went on, though its progrefs was retarded by various interruptions and accidents; till, at the latter end of August, when the feventh course was nearly finished, a violent storm arose, which carried away the shears and triangles, together with two of the largest stones which had been left chained on the rock! yet notwithstanding these and various other difficulties, the ninth course was completed by the

end of September.

" Being now arrived at the eve of October (lays Mr Smeaton), I maturely confidered our fituation; and finding that we had been 18 days in completing the last course, whereas the former one was begun and finished in five, though the weather, both on shore and above head, had remained to all appearance much the fame; I from thence concluded it to be very probable, we might not get another course completed in the compass of the month of October: So that when I restected on the many disasters that we had suffered last year by continuing out to the month of November, and how little work we in reality did after this time, it appeared to me very problematical whether we might be able, with every possible exertion, to get another course finished this season; and considering how very ineligible it was to have a courfe lie open during the winter in this flage of the work, and that we had now got three complete courses established above the top of the rock, the fum of whose height was four feet fix inches; and that we could not leave the work in a more defenfible state, whether as relative to the natural violence thaw, on the coast of Glamorganshire, it exceeded, in of the fea, or the possibility of external injuries from these considerations, it appeared to me highly prowork; and in wet and dry, or wholly wet, was far fu- per to put a period to the outwork of the prefent seafon."

At the commencement of the following year, 1758, equal the best merchantable Portland stone in solidity the weather proved very tempestuous till March; and on vifiting the rock, they discovered that the great buoy on the moorings had been carried away; nor were the mooring chains, though fought with the greatest perfeverance, recovered till the middle of May. In confequence of this delay, and from other accidents, the tenth course of the building was not completed till the 5th of July. From this time, the progress was without any very material interruption; fo that on the 26th of September the 25th course, being the first or the superstructure, was finished. The work was now so far advanced, that Mr Smeaton made a propofal to the Trinity Board and to the proprietors, of exhibiting a light during the enfuing winter; and for this purpole he continued his operations longer than he otherwise would have done, in order to complete the first room, and make it habitable; but foul weather coming on, he was obliged to quit the rock, and returned to Plymouth. A storm ensued; and, on the next morning, looking out with his telescope, he could discern the house with the sea breaking over it, but nothing of the buss. On the following day, the air being more clear, several of whom were in their shirts, and in great distress. he had a distinct view of the building; but the buss I hone. was really gone. This was a day of double regret, as it likewise brought a negative on his proposal for exhibiting a light from the house during the winter. The buss had run into Dartmouth harbour; she was brought home; and the work on the rock being fecured against the winter, the operations of the third feason were

During the early part of 1759, Mr Smeaton was employed in London in forming and making out the necessary designs for the iron rails of the balcony, the cast iron, the wrought iron, and the copper works for the lantern, together with the plate glass work. It was not till the 22d of June that he arrived at Plymouth. As the moorings had been again loft, new chains were provided, and the bufs was once more fixed in her situation. On the 5th of July he landed on the rock, and found every thing perfectly found and firm, without the least perceptible alteration, excepting that the cement, used in the first year, now in appearance approached the hardness of the moorstone; and that used in the last year had the full hardness of Portland; but on hauling up the stones for the next circle from the store-room, where they had been deposited, he had the mortification to find only feven instead of eight. It was imagined that a body of falling water, making its way through the open ribs of the centre, had washed this stone out of the store-room door, though it weighed between four and five hundred weight.

The progress of the work, however, was now such, that a whole room, with its vaulted cover, was built

complete in feven days.

On the 17th of August the main column was com-

On the 27th Mr Richardson and his company left the Edystone, and gave an account that they had lived . in it fince the 23d, having found it much more warm

than the buss's hold and cabin.

They had now finished every thing belonging to the masonry. The work of the cupola was going on briskly in the yard at Mill-bay, though it was retarded by the fuccessive illnesses of the two principal coppersmiths. However, by the exertions of Mr Smeaton, who was himself ready to work at every business, all matters were put in fuch forwardness, that by the 8th of September there was nothing to prevent the frame of the lantern from being fixed in its place but bad weather. It was not till the 15th that the weather permitted the boats to deliver their cargoes. The 16th was remarkably fine; fo that by the evening the whole frame of the lantern was screwed together, and fixed in its place. On the 17th, which was also exceedingly fine, the cupola was brought out, and the shears and tackle were fet up for hoisting it.

"This (fays Mr Smeaton) perhaps may be accounted one of the most difficult and hazardous operations of the whole undertaking; not fo much on account of its weight, being only about 11 cwt. as on account of the great height to which it was to be hoisted clear of the building, and fo as, if possible, to avoid such blows as might bruife it. It was also required to be hoisted a confiderable height above the balcony floor; which, though the largest base that we had for the shears to fland on, was yet but 14 feet within the rails, and therefore narrow in proportion to their height. About moon the whole of our tackle was in readiness; and in the afternoon the Weston (boat) was brought into the Edystone. gut, and in less than half an hour her troublesome cargo was placed on the top of the lantern without the least damage. During the whole of this operation it pleafed God that not a breath of wind discomposed the furface of the water, and there was the least swell about

the rocks I had observed during the season.

"Tuesday, September 18th, in the morning, I had the fatisfaction to perceive the Edystone boat, on board of which I expected the ball to be; and which being double gilt, I had ordered the carriage of it to be carefully attended to. The wind and tide were both unfavourable to the veffel's getting foon near us; therefore, being defirous to get the ball screwed on before the shears and tackle were taken down, one of the yawls was difpatched to bring it away. This being done, and the ball fixed, the shears and tackle were taken down, which took up nearly as much time as was employed in fetting them up; that is, near 12 hours each, in the whole, to do the work of an hour. - I must observe, that by choice I screwed on the ball with mine own hands, that in case any of the screws had not held quite tight and firm, the circumstance might not have been slipped over without my knowledge; being well aware, that even this part would at times come to a confiderable stress of wind and sea, and which could not be replaced without fome difficulty in case any thing should fail .- It may not be amiss to intimate to those who may in future have to perform the same operation, that the fcaffold on which this was done confifted of four boards only, well nailed together, at fuch diffances as to permit it to be lifted over the ball when done with. It rested on the cupola, encompassing itsneck; and Roger Cornthwaite, one of the masons, placed himself on the opposite side upon it, to balance me while I moved round to fix the screws."

Respecting the disposition of the internal part of the edifice, Mr Smeaton fixed the beds in the uppermost room, and the fire-place, which constituted the kitchen, in the room below it; whereas, in the late house, the upper room was the kitchen, and the beds were placed in one of the rooms below; the confequence of which was, that the beds and bedding were generally in a very damp and difagreeable state. The present disposition. has perfectly answered the end proposed, as nothing can be more completely dry than the two habitable

On the 1st of October, every thing being finished, and the chandeliers hung, there was nothing to hinder a trial by lighting the candles in the day time. Accordingly 24 candles were put into their proper places, and were continued burning for three hours, during which time it blew a hard gale; and a fire being kept at the same time in the kitchen, they both operated without any interference; not any degree of smoke appearing in the lantern nor in any of the rooms; and by opening the vent holes, which had been made in the bottom of the lantern for occasional use, it could be kept quite cool; whereas, in the late light-house, it used to be so hot, especially in the summer, as to give much trouble by the running of the candles.

All being thus in readiness, and a conductor, in case of lightning, being adapted to the building, notice was given to the Trinity-house that the light would be exhibited on the 16th of October 1759. The season of

Tiplione, the year being now advanced to that which was always very precarious, the Neptune buss was unmoored, and on the 9th of October she came to an anchor in Plymouth harbour .- " And thus (fays Mr Smeaton), after innumerable difficulties and dangers, was a happy period put to this undertaking, without the loss of life or limb to any one concerned in it, or accident, by which the work could be faid to be materially retarded."

With regard to subsequent occurrences, it is truly observed, that the best account is, that, after a trial of 40 years, which have elapfed fince the finishing of the building, it still remains in its original good condition. A few particulars are however interesting. On the 19th of October Mr Smeaton, with Mr Jessop, &c. vifited the house, and, landing, found all well. Henry Edwards, one of the light keepers, gave an account that they lighted the house as they were directed, and found the lights to burn fleadily, notwithflanding it blew very hard; that they had the greatest seas on the days immediately preceding the lighting; and that then the waves broke up fo high, that had they not been thrown off by the cove course, they would have endangered breaking the glass in the lantern: that when the seas broke the highest, they had experienced a sensible motion; but that, as it was barely perceptible, it had oc-

casioned them neither fear nor surprize.

During his stay at Plymouth, in the times of stormy weather, Mr Smeaton took several opportunities of viewing the light-house with his telescope from the Hoa; and also from the garrison, both which places were fufficiently elevated to fee the base of the building, and the whole of the rock at low water in clear weather; and though he had many occasions of viewing the unfinished building when buried in the waves in a from at fouth-west; yet having never before had a view of it under this circumstance in its finished state, he was aftonished to find that the account given by Mr Winstanley did not appear to be at all exaggerated. At intervals of a minute, and sometimes of two or three, when a combination happened to produce one overgrown wave, it would strike the rock and the building conjointly, and fly up in a white column, enwrapping it like a sheet, rising at least to double the height of the house, and totally intercepting it from the fight; and this appearance being momentary, both as to its rifing and falling, he was enabled to judge of the comparative height very nearly by the comparative spaces, alternately occupied by the house and by the column of water in the field of the telescope.

The year 1750 concluded with some very stormy weather; and in January 1760, Mr Jeffop vifited the house, but could not land. He got a letter, however, from Henry Edwards, acquainting him that therehad been fuch very bad weather that the fea frequently ran over the house; so that for 12 days together they could not open the door of the lantern nor any other. He said, "the house did shake as if a man had been up in a great tree. 'The old men were almost frighted out of their lives, wishing they had never feen the place, and curfing those that first perfuaded them to go there. The fear feized them in the back; but rubbing them with oil of turpentine gave them relief." He farther mentioned, that on the 5th of December, at night, they had a very great florm; fo that the ladder, which was Hashed below the entry door, broke loose, and was washed away. Alfo, on the 13th, there was fo violent a ftorm of Edyllo: wind that he thought the house would overset; and at Eglantin midnight the sea broke one pane of glass in the lantern. They had a very melancholy time of it, having also had a great deal of thunder and lightning.—" The storms (observes Mr Smeaton) which the building has now fustained without material damage, convince us, and every one, of the stability of the stone light house, except those (who were not a few) who had taken a notion that nothing but wood could refift the fea upon the Edystone rocks; who said, that though they allowed it was built very strong, yet if such a storm as had destroyed Winstanley's light-house was again to happen, they doubted not but it must share the same sate. The year 1762 was ushered in with stormy weather, and indeed produced a tempest of the first magnitude; the rage of which was fo great, that one of those who had been used to predict its downfal was heard to fay, If the Edyttone light-house is standing now, it will fland till the day of judgment. And, in reality, from this time, its existence has been so entirely laid out of mens minds, that whatever ftorms have happened fince, no inquiry has ever been made concerning it."

For the length of this detail we cannot bring ourfelves to make any apology. If there be a few of our readers to whom it may appear tedious, we are perfuaded that there are many more to whom it will be in a high degree interesting; while such of them as are engineers will derive instruction even from this very a-

bridged history of the Edytlone light-house.

EFFECTION, denotes the geometrical construction of a proposition. The term is also used in reference to problems and practices, which, when they are deducible from, or founded upon, some general propositions, are

called the geometrical effection of them.

EGLANTINE (Fabre de), was born at Chalons in Champagne. He was early educated, by the care of his parents, in polite literature and natural philosophy. From his youth he felt an invincible inclination to court the muses; and in the year 1786 he published, in a French periodical work, intitled Les Etrennes du Parnasse, a little poem called Chalons sur Marne, in which he drew a very charming picture of the moral pleasures that were to be found in that place and its neighbourhood. This piece, however, was then confidered as a juvenile composition, and fell very short of that high degree of celebrity which the author afterwards attained to. In the years 1789 and 1790 he published two well known comedies, Le Philinte, and L'Intrigue Epiftolaire. Befides his talents for writing comedics, he felt, like Moliere, an inclination to perform parts on the stage. He accordingly acted his own plays in the theatres of Lyons and Nimes.

Being, like the greater part of French wits and philosophers, an avowed enemy to religion and civil subordination, he was thought to have sufficient merit to be removed from the office of fabricating comedies to that of fabricating constitutions. Accordingly, in 1792, he was chosen (we believe by the influence of the Girondinc faction) a deputy to the National Convention. In that affembly, during the winter and the spring of 1793, he acted a part certainly not very commendable, though every way worthy of the pupil of the economists. At that period the Girondine party was the most powerful; and it was very generally reported among

partine the best informed people at Paris, that Fabre contributed, together with Danton and Robespierre, to the famous massacre of the 31st of May, when the Girondine faction was overthrown by a popular infurrection. What gives the appearance of authenticity to this report is, that Fabre himself some days afterwards observed to a friend, that the domineering spirit of the Girondines, who had engroffed all power and office, had induced him and his colleagues, in order to shake off the yoke, to throw themselves into the hands of the Sansculoterie; that he could not help, however, foreboding dangerous consequences from that day, 31st of May, as the same mob which they had taught to despise the legislature might, at the infligation of another faction, overthrow him in his turn. Thus Fabre appeared to have a prefentiment of his own future destiny.

On the overthrow of the Girondine party, and the establishment in power of the Sansculoterie, Fabre began to act a confiderable part. He was appointed member of the Committee of Public Instruction; in which station, in the month of August 1793, he gave his vote for suppressing all academies and literary corporations which, from their privileges and aristocratic foirit, were confidered as unfriendly to a truly republican government. In October 1793, he submitted to the National Convention the plan of a new calendar,

which was afterwards adopted.

The reader who will take the trouble to turn to the article Revolution, no 184, Encycl. may fee that calendar, and be able to judge for himself whether it evinces the childifhness or the science of its author. A journalist of our own indeed, who seems to admire every thing that is new and odd, fays, that the accuracy and regularity with which it was executed, evinced an uncommon degree of knowledge in mathematics and natural philosophy, and failed not to reflect on its author great reputation! Indeed! Had the Sansculotes so soon forgotten their "guides, philosophers, and friends," D'Alembert, and Condorcet, as to confider this exploit as sufficient to place its author in the temple of same Eglantine among the fons of science? Our journalist, however, Elections. admits, that it gave birth to a pleasant pamphlet, intitled Le Législateur à la Mode; in which it was demonstrated, that the 31st chapter of the travels of Anacharfis, by the Abbe Barthelemy, where the description of the ancient Greek calendar is introduced, had furnished no inconsiderable part of the plan of the new Fabrine calendar.

The Sansculoterie had now become too powerful to be tolerated any longer. In the winter of 1794, that faction was divided into two parts, the Jacobins and the Cordeliers, or, in other words, the Robespier-rists and the Dantonists. Fabre was of the faction of Danton, and was confined with Danton's adherents in the prison of the Luxemburg. From that prison he wrote a number of letters, which were afterwards printed. These letters are highly extolled as beautiful descriptions of sensibility and talents in distress. After a month's imprisonment, Fabre was, with many others, executed in the place de la Revolution, in April 1794, in the 35th year of his age. His fentence, we believe, was unjust; but death he had more than merited.

ELASTICITY. In addition to the article in the Encyclopædia, see, in this Supplement, the view of Boscovich's theory of natural philosophy, no 26.

ELECTIONS, or CHOICE, fignify the feveral different ways of taking any number of things proposed, either separately, or as combined in pairs, in threes, in fours, &c.; not as to the order, but only as to the number and variety of them. Thus, of the things a, b, c, d, e, &c. the elections of

one thing are (a,) $1 = 2^{x} - 1$, two things are (a, b, ab,) $3 = 2^2 - 1$,

three things are (a, b, c, ab, ac, bc, abc,) $7 = 2^3 - 1$, &c.; and of any number n, all the elections are $2^n - 1$; that is, one less than the power of 2 whose exponent is n, the number of fingle things to be chosen, either fea parately or in combination.

ELECTRICITY.

IVE cannot but be somewhat surprised that, among the many attempts which have been made by the philosophers of Britain to explain the wonderful phenomena which are classed under this name, no author of eminence, besides the Hon. Mr Cavendish and Lord Mahon, have availed themselves of their susceptibility of mathematical discussion; and our wonder is the greater, because it was by a mathematical view of the subject, in the phenomena of attraction and repulfion, that the celebrated philosopher Franklin was led to the only knowledge of electricity that deserves the name of science; for we had scarcely any leading facts, by which we could class the phenomena, till he published his theory of positive and negative, or plus and minus, electricity. This is founded entirely on the phenomena of attraction and repulsion. These furnish us with all the indications of the presence of the mighty agent, and the marks of its kind, and the measures of its force. Mechanical force accompanies every other appearance; and this accompanyment is regulated in a

are firstly mechanical, producing local motion in the fame manner as magnetism or gravitation produce it. One should have expected that the countrymen of Newton, prompted by his fuccess and his fame, would take to this mode of examination, and would have endeavoured to deduce, from the laws observed in the action of this motive force, an explanation of other wonderful phenomena, which are inseparably connected with those of attraction and repulsion.

But this has not been the case, if we except the labours of the two philosophers above mentioned, and a few very obvious positions which must occur to all the inventors and improvers of electrometers, batteries, and

other things of measurable nature.

This view has, however, been taken of the subject by a philosopher of unquestioned merit, Mr Æpinus of the Imperial Academy of St Petersburgh. This gentleman, struck with the refemblance of the electrical properties of the tourmalin to the properties of a magnet, which have always been confidered as the fubdeterminate manner. Many of the effects of electricity ject of mathematical discussion, fortunately remarked a

wonderful fimilarity in the whole feries of electrical and magnetical attractions and repulsions, and fet himself feriously to the classification of them. Having done this with great success, and having maturely reflected on Dr Franklin's happy thought of plus and minus electricity, and his consequent theory of the Leyden phial, he at last hit on a mode of conceiving the whole subject of magnetism and electricity, that bids fair for leading us to a sull explanation of all the phenomena; in as far, at least, as it enables us to class them with precision, and to predict what will be the result of any proposed treatment. He candidly gives it the modest name of

a hypothesis.

This was published at St Petersburg in 1759, under the title of Theoria Electritatis et Magnetismi, and is unquestionably one of the most ingenious and brilliant performances of this century. It is indeed most furprifing that it is so little known in this country. This, we imagine, has been chiefly owing to the very flight and almost unintelligible account which Dr Priestley has given of it in his history of electricity; a work which professes to comprehend every thing that has been done by the philosophers of Europe and America for the advancement of this part of natural science, and which indeed contains a great deal of instructive information, and, at the same time, so many loose conjectures and infignificant observations, that the reader (especially if acquainted with the Doctor's character as an unwearied bookmaker) reasonably believes that he has let nothing flip that was worthy of notice. do not pretend to account for the manner in which Dr Priestley has mentioned this work. so much, and so deservedly celebrated on the continent. We cannot think that he has read it fo as to comprehend it, and imagine, that feeing fo much algebraic notation in every page, and being at that time a novice in mathematical learning, he contented himself with a few scattered paragraphs which were free of those embarrassments; and thus could only get a very imperfect notion of the fystem. The Hon. Mr Cavendish has done it more justice in the 61st volume of the Philosophical Transactions, and confiders his own most excellent differtation only as an extension and more accurate application of Æpinus's Theory. That we have not an account of this exposition of the Franklinian theory of electricity in our language, is a material want in British literature; and we trust, therefore, that our readers will be highly pleafed with having the ingenious discoveries of the great American philosopher put into a form so nearly approaching to a system of demonstrative science.

We propose, therefore, in this place, to give such a brief account of Æpinus's theory of electricity, as will enable the reader to reduce to a very simple and easily remembered law all the phenomena of electricity which have any close dependence on the mechanical effects of this powerful agent of nature; referring for a demonstration of what is purely mathematical to Sir Isaac Newton's Principia, and the Dissertation by Mr Cavendish already mentioned, except in such important articles as we think ourselves able to present in a new, and, we hope, a more familiar form. We do not mean, in this place, to give a system of philosophical electricity, nor even to narrate and explain the more remarkable phenomena. Of these we have already given a wast collection in the article Electricity, Encycl.

We confine ourselves to the phenomena which may be called mechanical, producing measurable motion as their immediate effect; and thus giving us a principle for the mathematical examination of the cause of electrical phenomena. We shall consider the reader as acquainted with the other physical effects of electricity, and shall fractionally refer to them for proofe

frequently refer to them for proofs.

Moreover, as our intention is merely to give a fynoptical view of this elaborate and copious performance of Mr Æpinus, hoping that it will excite our countrymen to a careful perufal of fo valuable a work, we shall omit most of the algebraic investigations contained in it, and present the conclusions in a more familiar, and not less convincing, form. At the same time we will insert the valuable additions made by Mr Cavendish, and many important particulars not noticed by either of those gentlemen.

HYPOTHESIS OF ÆPINUS.

THE phenomena of electricity are produced by a Hypothian fluid of peculiar nature, and therefore called the ELECTRIC FLUID, having the following properties:

1. Its particles repel each other, with a force decrea-

fing as the distances increase.

2. Its particles attract the particles of some ingredient in all other bodies, with a force decreasing, according to the same law, with an increase of distance; and this attraction is mutual.

3. The electric fluid is dispersed in the pores of other bodies, and moves with various degrees of facility through the pores of different kinds of matter. In those bodies which we call non-electrics, such as water or metals, it moves without any perceivable obstruction; but in glass, rosins, and all bodies called electrics, it moves with very great difficulty, or is altogether immoveable.

4. The phenomena of electricity are of two kinds;
1. Such as arise from the actual motion of the fluid from a body containing more into one containing less of it.
2. Such as do not immediately arise from this transference, but are instances of its attraction and repulsion.

These things being supposed, certain consequences necessarily result from them, which ought to be analogous to the observed phenomena of electricity, if this hypothesis be complete, or some farther modification of the assumed properties is necessary, in order to make

the analogy perfect.

Suppose the body A (fig. 1.) to contain a certain quantity of suid. Its particles adjoining to the sur-Plate face, such as P, are attracted by the particles of common matter in the body, but repelled by the other particles of the suid. The totality of the attractive forces acting on P may be equal to the totality of the repulsive forces, or may be unequal. If these two sums are equal, P is in equilibrio, and has no tendency to change its place. But there may be such a quantity of suid in the body, that the repulsions of the suid exceed the attractions of the common matter. In this case, P has a tendency to quit the body, or there is an expulsive force acting on it, and it will quit the body if it be moveable. Because the same must be admitted in respect of every other particle of moveable suid, it is plain that there will be an efflux, till the attraction of the common matter for the particles of suid is equal.

I

requal to the repulsion of the remaining sluid. On the other hand, if the primitive repulsion of the sluid acting on the particle P be less than the attractions of the common matter, there will be the same, or at least a similar, superiority of attraction acting on the sluid residing in the circumambient bodies; and there will be an influx from all hands, till an equilibrium be restored.

Hence it follows, that there may always be affigned to any body such a quantity of suid that there shall be no tendency either to efflux or influx. But if the quantity be increased, and nothing prevent the motion, the redundant sluid will flow out; and if the proper quantity be diminished, there will be an influx of the surrounding sluid, if not prevented by some external force. This may be called the body's NATURAL QUANTITY; because the body, when left to itself, will always be reduced to this state.

If two bodies, A and B, contain each its natural quantity, they will not exert any fensible action on each other: for, because the fluid contained in B is united by attraction to the common matter, and is also repelled by the fluid in Λ , it necessarily follows, that the whole body B is repelled by the fluid in A. But, on the other hand, the matter in A attracts the fluid in B, and confequently attracts the whole body B: Similar action is exerted by B on A. These contrary forces are either equal, and destroy each other, or unequal, and one of them prevails. This equality or inequality evidently depends on the quantity of fluid contained in one or both of the bodies (no 7.). Now it is known that bodies left entirely to themselves neither attract nor repel; and it follows from the hypothetical properties of the fluid, that if there be either a redundancy or deficiency of fluid, there will be an efflux or influx, till the attractions and repulsions balance each other. Therefore the internal state of two bodies which neither attract nor repel each other, is that where each contains its natural quantity of electric

In order, therefore, to conceive distinctly the state of a body containing its natural quantity, and to have a distinct notion of this natural quantity, we must suppose that the quantity of suid competent to a particle of matter in A repels the suid competent to a particle of matter in B, just as much as it attracts that particle of matter; and also, that the sluid belonging to a particle of matter in A, repels the sluid belonging to a particle of matter in B, just as much as the particle of matter in A attracts it. Thus the whole sluid in the one repels the whole sluid in the other as much as it attracts the whole matter.

Since this must be conceived of every particle of common matter in a body, we must admit, that when a body is in its natural state, the quantity of electric sluid in it is proportional to the quantity of matter, every particle being united with an equal quantity of sluid. This, however, does not necessarily require that different kinds of matter, in their natural or saturated state, shall contain the same proportion of sluid. It is sufficient that each contains such a quantity, uniformly distributed among its particles, that its repulsion for the sluid in another body is equal to its attraction for the common matter in it. It is, however, more probable, for reasons to be given afterwards, that the quantity of

SUPPL. VOL. I. Part II.

electric fluid attached, or competent, to a particle of all kinds of matter is the same.

We shall now consider more particularly the immediate results of this hypothesis, in the most simple cases, from which we may derive some elementary propositions.

Since our hypothesis is accommodated to the fact, Electric that bodies in their natural state, having their natural phenomena quantity of electric study, are altogether inactive on each redundancy other, by making this natural quantity such, that its or deficient mutual repulsion exactly balances its attraction for the cy in sludy, common matter—it follows, that we must deduce all total or parthe electric phenomena from a redundancy or deficiency of electric fluid. This accordingly is the Franklinian doctrine. The redundant state of a body is called by Dr Franklin positive or plus electricity, and the deficient state is called NEGATIVE OR MINUS ELECTRICITY.

A body may contain more than its natural quantity, or lefs, in every part, or it may be redundant in one place and deficient in another. These different conditions will exhibit different appearances, which must be considered first of all.

Let the body A (fig. 1.) be supposed in its natural Action of state throughout, which we shall generally express by the redundarying that it is saturated; and let us express the dant studing quantity of study equivers for its saturation by the symmother matter, bol Q. Let P be a superficial particle of the study. It how comis attracted by the common matter of the body (which we shall in future call simply the matter), and it is repelled equally by the sluid. Let us call the attraction a, and the repulsion r. Then the force with which the superficial particle is attracted by the body, must be a - r, and a - r must be a - r, because a - r. Let the quantity a - r of sluid be added to the body, and uniformly distributed through its substance. Then, because we must admit that the action is in proportion to the quantity of acting sluid, and this is now a - r, and therefore

P is repelled by the whole fluid with the force $\frac{Q+f\times r}{Q}$, or $\frac{Qr}{Q}+\frac{fr}{Q}$, or $r+\frac{fr}{Q}$. But it is attracted by the common matter in the same manner as before, that is, with a force =a. Therefore the whole action on P is $=a-r-\frac{fr}{Q}$. But a-r=0. Therefore the whole action on P is $=\frac{fr}{Q}$; that is, P is repelled with the force $\frac{fr}{Q}$.

This will perhaps be as distinctly conceived by recollecting, that as much of the fluid as was necessary for faturation, that is, the quantity Q, puts the particle P in equilibrio; and therefore we need only consider the action of the redundant fluid f. To find the repulsive force of this, say $Q: f = r: \frac{f}{Q}$, and prefix the sign —; because we are to consider attractions as positive, and repulsions as negative, quantities.

Unless, therefore, the particle P be withheld by some o-4 B ther 562

States of a fing efflux or influx.

13.

ther force, it will quit the body, being expelled by a force And as every superficial particle is in a similar fituation, we see that there will be an efflux from an overcharged body, till all the redundant fluid has quit-This efflux will indeed gradually diminish as the expelling force $\frac{fr}{O}$ diminishes; that is, as f diminishes, but will never cease till f be reduced to nothing. But if there be either an external force acting on the superficial sluid in the opposite direction, or some internal obstruction to its motion, the efflux will stop when the remaining expelling force is just in equilibrio with

this external force, or this obstruction. On the other hand, if the body contains less than its natural quantity of fluid, there will be an influx from without; for if there be a deficiency of fluid = f, the particle P will be repelled with the force $\frac{Q - f \times r}{Q}$,

 $= r - \frac{fr}{Q}$. It is attracted with the force a; and therefore the whole action is $= a - r + \frac{fr}{Q}, = + \frac{fr}{Q}$ (because a - r = 0); that is, P is attracted with the force $\frac{fr}{Q}$. Fluid will therefore enter from all quarters, as long as there is any deficiency of the quantity necesfary for faturation, unless it be opposed by some external

force, or hindered by some internal obstruction. When there is a deficiency of fluid, there is a redundancy of matter, such that its attraction for external fluid is equal to the repullion of a quantity f of fluid. This confirms the assumption in no 10, that the action of a body on the electric fluid depends entirely on the redundant fluid, or the redundant matter of the body.

are ideo-

The efflux or influx may be prevented, either by fur-How bodies rounding the body with substances, through the pores electrics or of which the fluid cannot move at all, or by the body itself being of this constitution. And thus we see, that the very circumstance of being impervious to the sluid, or completely permeable, renders the body capable or incapable of permanently exhibiting electrical phenomena, if furrounded by permeable bodies. This circumstance alone, therefore, is sufficient to constitute the difference between electrics per se, and non-electrics.— Here, then, is a numerous class of phenomena, which receive an explanation by this hypothetical constitution of the electric fluid. All electrics per se are bodies sit for confining electricity in bodies which are rendered capable (by whatever means) of producing electrical phenomena; and no conductor, or fubstance which allows the electricity to pass through it, can be made electric by any of the means which produce that effect in infulators. And it is well known, that the electricity of electrics is vaftly more durable than that of non electrics in fimilar fituations. It is true, indeed, that an electric, which has been excited fo as to exhibit electric phenomena with great vivacity, loses this power very quickly if plunged into water, or any other conducting body. But this is owing to the redundancy or defi-ciency being quite superficial, so that the parts which are disposed to give out or to take in the fluid are in immediate contact with the conducting matter. That

the redundancy or deficiency is superficial, follows from this hypothesis; for when the surface is overcharged by the means employed for exciting, the impermeability of the electric per se prevente this redundant fluid from penetrating to any depth; and when the surface has been rendered deficient in fluid, the fame impermeability prevents the fluid from expanding from the interior parts, fo as to contribute to the replenishing the superficial stratum with fluid. If, indeed, we could fall on any way of overcharging the interior parts of a glass ball, or of abstracting the natural quantity from them, it is highly probable, that it would continue to attract or repel even after it had been plunged in water. Although the furrounding water would instantly take off the sluid redundant contained in the very furface, the repulsion of the fluid in the internal parts would ftill be fenfible: nay, if a very small permeability be supposed, the body would again become overcharged at the surface; just as we see, that when we plunge a red hot ball of iron into water, and take it out again immediately, it is black on the furface, and may be touched with the finger; but in half a minute after, it again becomes red hot. Perhaps this may be accomplished with a globe of sealing wax, which is permeable while liquid, by electrifying it in a particular way while in that state, and allowing it to freeze. But the reader is not far enough advanced in the hypothesis to understand the process which must be followed. He cannot but recollect, however, many examples in coated glass, &c. where the electricity is most pertinaciously retained by a surface in very close contact with conductors.

Let us now suppose a body N S (fig. 2.), contain-Confeq ing in the half NA a quantity f of redundant fluid, ces of and in the half AS let there be a deficiency g of fluid; quable that is, let there be a quantity of matter unfaturated, fluid. 1 and fuch as will attract fluid as much as the quantity gtion o of fluid would repel it. Let the fluid necessary for the ternal faturation of each half of NS be Q, as before. Let the attraction of the whole matter of NA for a particle of fluid at N be a; and let r be the repulsion exerted on the same particle N by the whole uniformly distributed fluid in NA and let r' be the repulfion exerted by the fame quantity of fluid in the remote part SA. Then the force with which the particle N or S is attracted by the merely faturated body NS must be = a - r - r'. This is evidently nothing, if the body be in its natural state. But as NA contains the redundant fluid f, and SA is deficient by

the quantity g, the whole action must be $a - \frac{Q + f \times r}{Q}$

But because a - r - r' = o, the

action becomes $=\frac{g r'-fr}{Q}$, or because r is greater than r', the particle N is repelled with the force $\frac{fr-gr'}{Q}$. In like manner, the particle S is attracted with the force $\frac{gr-fr'}{Q}$.

In the mean time, a particle C, fituated at the mide 2. A dle, must be in equilibrio, if the body be in its natural on the ftate, being equally attracted, and also equally repelled, tained on both fides. But as we find the on both fides. But as we suppose that NA is overchar-

ged with the quantity f, C must be repelled in the direction CS with the force $\frac{fr}{Q}$. And if we also suppose that AS is deficient by the quantity g, C is attracted in the direction CS with a force $\frac{g r}{Q}$. Therefore, on the whole, it is urged in the direction CS with the force

 $\frac{fr+gr}{Q}$, or $\frac{f+g\times r}{Q}$.

Hence we learn, that as long as there is any redundancy in AN, and deficiency in AS, there is a tendency of the redundant fluid to move from N toward S; and, if the body be altogether permeable by the electric fluid, we cannot have a permanent state till the fluid is fimilarly distributed, and equally divided, between the two halves of NS. Therefore a state like that affumed in this example cannot be permanent in a conducting body, unless an external force act on it; but it may subsist in a non-conductor, and in a lesser de-

gree, in all imperfect conductors.

17 1 ill be

? ure of

It is necessary, in this place, to consider a little the t boltrue nature of that refistance which must be assigned to the motion of the electric fluid through the pores of the body. If it refemble the refistance opposed by a perfect fluid, arifing folely from the inertia of its particles, then there is no inequality of force fo minute but that it will operate a uniform distribution of the sluid, or at least a distribution which will make the excess of the mutual attractions and repulfions precifely equal and oppolite to the external force which keeps it in any state of unequal distribution. But it may refemble the refistance to the descent of a parcel of small shot dissemi-nated among a quantity of grain, or the resistance to motion through the pores of a plastic or ductile body, fuch as clay of lead. Here, in order that a particle may change its place, it must overcome the tenacity of the adjoining particles of the body. Therefore, when an unequal distribution has been produced by an external force, the removal or alteration of that force will not be followed by an equable distribution of the sluid. In every part there will remain fuch an inequality of distribution, that the want of equilibrium between the electric attractions or repulsions is balanced by the tenacity of the parts.

We learn farther from the foregoing propositions, that a particle at N is less repelled than if the part AS were overcharged as AN is: for in that case, it would be ex-

pelled by a force $\frac{f \times r + r'}{Q}$, which is much greater than $\frac{f \cdot r - g \cdot r_i}{Q}$. And, in like manner, the particle S

is attracted with less force than it would be if NA were

equally undercharged with SA.

The condition of the body now described may be changed by different methods. The redundant fluid in AN may flow into AS, where it is deficient, till the whole be uniformly distributed; or slaid may escape from AN, and fluid may enter into AS, till the body be in its natural state. The first method will be so much the flower as the body is lefs permeable, or more remarkably electric per fe; and the fecond method will be flower than if the whole body were overcharged or undercharged.

What we have been now faying of a body NS that

is overcharged at one end, and undercharged at the other, and capable of retaining this state, is applicable, in every particular, to two conducting bodies NA and SA', having a non-conducting body Z interpofed between them, as in fig. 3. All the formulas, or expresfions of the forces which tend to expel or to draw in fluid, are the fame as before. Perhaps this is the best way of forming to ourselves a distinct notion of the body that is redundant in fluid at one end, and deficient at the other. And we perceive, that the state of the two bodies, separated by the electric Z, will be more permanent when one is overcharged, and the other undercharged, than if both are either over or undercharged.

It must be remarked, that the quantities f and g were A body taken at random. They may be fo taken, that the may be inforce with which the fluid tends to efcape at N, or to active or enter at S, may be nothing, or may even be changed where it is to their opposite. Thus, in order that there may be redundant no tendency to escape from N, we have only to suppose or deficient.

gr'-fr=0, or g:f=r:r', and $g=\frac{fr}{r'}$. In this case, the particle at N is as much attracted by the redundant matter in SA as it is repelled by the redundant fluid in NA.

When the extremity N is rendered inactive in this 23 manner, the condition of the other extremity S is conformal fiderably changed. To discover this condition, put for this. $\frac{fr}{r}$ in place of g in the formula $\frac{gr-fr'}{Q}$, which exprefes the attraction for a particle at S, and we obtain $\frac{f \times r^2 - r'^2}{Q r'}$ On the other hand, we may have the redundancy

and deficiency so balanced, that there shall be no tendency to influx at S. For this purpose, we must make $g = \frac{fr'}{r}$. When this obtains at S, the action at N will be had by putting $\frac{fr'}{r}$ in place of g in the formula $\frac{fr - gr'}{Q}$, and this will give us $\frac{f \times r'^2 - r^2}{Qr}$ for the force repelling a particle at N.

When the tendency to efflux or influx is induced in this manner, by a due proportion of the redundancy and deficiency of electric fluid, the part of the body where this obtains is by no means in its natural state, and may contain either more or less than its natural quantity. But it neither acts like an overcharged nor like an undercharged body, and may therefore be called NEU-TRAL. The reader who is conversant with electrical experiments, will recollect numberless instances of this, and will also recollect that they are important ones. Such, for example, is the case with the plates and covers of the electrophorus. These circumstances, therefore, claim particular attention.

As the quantities f and g may be so chosen, that the apparatus thall be neutral, either at S or at N; they may likewise be so, that either end shall exhibit either the appearance of redundancy or deficiency. Thus, instead of neutrality at N, we may have repullion, as at the first, by making g less in any degree than $\frac{fr}{r'}$. If, on the contrary, g be greater than $\frac{fr}{r'}$, the extremity N, tho' overcharged, will attract fluid. In like manner, if g

be less than $\frac{fr'}{r}$, the extremity S, although undercharged, will repel fluid .- We may make the following general remarks.

Both ends neutral at once.

1. Both extremities N and S cannot be neutral at the fame time: for fince the neutrality arises from the increased quantity of redundancy or deficiency at the other extremity, so as to compensate for its greater distance, the activity of that extremity must be proportionably greater on the fluid adjoining to its furface, whether externally or internally. When an overcharged extremity is rendered neutral, the other extremity attracts fluid more strongly; and when a deficient extremity is rendered neutral, the other repels sluid more strongly. All these elementary corollaries will be fully verified afterwards, and give clear explanations of the most curious phenomena.

2. We have been supposing, that the redundant sluid is uniformly spread, and that the body is divided into equal portions; but this was merely to fimplify the procedure and the formulæ. The reader mult fee, that the general conclusions are not affected by this, and that fimilar formulæ will be obtained, whatever is the disposition of the fluid. We cannot tell in what manner the redundant fluid is disposed, even in a body of the simplest form, till we know what is the variation of its attraction and repulsion by a change of distance; and even when this has been discovered, we find it difficult in most cases, and impossible in many, to ascertain the mode of distribution. We shall learn it in some important cases, by means of various phenomena judicious-

ly felected.

A body may be confidered in many divisions, in some of which the fluid is redundant, and in others deficient. We may express the repulsion of the whole of this body in the same way as we express that of a body considered in two divisions, using the letters f, g, h, &c. to express the quantities of redundant or deficient fluid in each portion, while Q expresses the quantity necessary for faturating each of them; and the repulsion at different diffances may be expressed by r, r', r'', r''', &c. as they are more and more remote; and we may express their action as attractive or repulsive by prefixing the fign + or —. Thus the attraction may be (fr-gr'+hr''-ir''), &c.

Sensible acelectrical bodies.

28.

Having obtained the expressions of the invisible actions of electrified bodies on the fluid within them, or furrounding them, let us now confider their fenfible actions on other bodies, producing motion, or tendencies

Here it is obvious, that the mechanical phenomena exhibited are what may be called remote EFFECTS of the acting forces. The immediate effects, or the mutual actions of the particles, are not observed, but hypothetically inferred. The tangible matter of the body is put in motion, in consequence of its connection with the fluid residing in the body, which stuid is the only fubject of the action of the other body.

In confidering these phenomena, we shall content ourtelves with a more general view of the actions which take place between the fluid or tangible matter of the one body, and the fluid or matter of the other, so as to gain our purpose by more simp le formulæ than those hi-therto employed. They were premised, however, because we must have recourse to them on many very im-

portant particular occasions.

Let there be two bodies, A and B, in their natural state. Let the tangible matter in A be called M, and let the fluid necessary for its saturation be called F, and let m and f be the tangible matter and the fluid in B. Let the mutual action between a fingle particle of fluid. and the matter necessary for its saturation be expressed by the indeterminate symbol z, because it varies by a change of diftance.

The actions are mutual and equal. Therefore when the motion of B by the action of A is determined, the niotion of A is also ascertained. We shall therefore only consider how A is affected. I. Every particle of shuid in A tends toward every particle of matter in B with the force z. The whole tendency of A toward B may therefore be expressed by z, multiplied by the product of F and m. 2. Every particle of fluid in A is repelled by every particle of fluid in B, with the fame force z. 3. Every particle of matter in A is attracted by every particle of fluid in B, with the same force. We may express this more purely and briefly thus:

1. F tends toward m with the force + Fmz 2. F tends from f with the force - Ffz 3. M tends toward f with the force + Mfz

Therefore the fensible tendency of A to or from B will be $= z \times F m + M f - F f$. But, by the hypothesis, the attraction of a particle of the fluid in A for a particle of the matter in B, is equal to its repulsion for the particle or parcel of the fluid attached or competent to that particle of matter. Therefore the attraction F m z. is balanced by the repulsion Ffz. Therefore there remains the attraction of the matter in A for the fluid in B unbalanced, and the body A will tend toward the body B with the force Mfz, or B attracts A with the force Mfz. A must therefore move toward B. And, by the 3d law of motion, B must move toward A with equal force.

But the fact is, that no tendency of any kind is ob-Complet ferved between bodies in their natural state. The hy-of the hy pothesis, therefore, is not complete. If we abide by it, Æpinus. as far as it is already expressed, we must farther suppose, that there is some repulsive force exerted between the bodies to balance the attraction of M for f. Mr Æpinus, therefore, supposes, that every particle of tangible matter repels another particle as much as it attracts the fluid necessary for its faturation. The whole action of B on A will now be $=z \times \overline{Fm} - \overline{Ff} - Mm + Mf$. F mz is balanced by F fz, and M mz by M fz, and no excess remains on either side.

Æpinus acknowledges, that this circumstance appear- Objection ed to himself to be hardly admissible; it seeming incon-answered ceivable, that a particle in A shall repel a particle in B, or tend from it, electrically, while it attracts it, or tends toward it, by planetary gravitation. We cannot conceive this; but more attentive confideration shewed him, that there is nothing in it contrary to the observed analogy of natural operations. We must acknowledge, that we fee innumerable instances of inherent forces of attraction and repulsion; and nothing hinders us from referring this lately discovered power to the class of primitive and fundamental powers of nature. Nor is there any difficulty in reconciling this repulsion with univerfal gravitation; for while bodies are in their natural

state, the electric attractions and repulsions precisely balance each other, and there is nothing to diffurb the phenomena of planetary gravitation; and when bodies are not in their natural electrical state, it is a fact that their gravitation is disturbed. Although we cannot conceive a body to have a tendency to another body, and at the same time a tendency from it, when we derive our notion of these tendencies entirely from our own consciousness of effort, endeavour, conatus, nisus accedendi seu recedendi, nothing is more certain than that bodies exhibit at once the appearances which we endeavour to express by these words We can bring the north poles of two magnets near each other, in which case they recede from each other; and if this be prevented by some obstacle, they press on this obstacle, and feem to endeavour to feparate. If, while they are in this state, we electrify one of them, we find that they will now approach each other; and we have a diffinct proof that both tendencies are in actual exertion by varying their distances, fo that one or other force may prevail; or by placing a third body, which shall be affected by the one but not by the other, &c. We do not understand, nor can conceive in the leaft, how either force, or how gravity, refides in a body; but the effects are past contradiction. It must be granted, therefore, that this additional circumstance of Æpinus's hypothesis has nothing in it that is repugnant to the observed phenomena of nature.

N. B. It is not necessary to suppose (although Mr Æpinus does suppose it), that every atom of tangible matter repels every other atom. It will equally explain all the phenomena, if we suppose that every particle contains an atom or ingredient having this property, and that it is this atom alone which attracts the particles of electrical fluid. The material atoms having this property, and their corresponding atoms of fluid, may be very few in comparison with the number of atoms which compose the tangible matter. Their mutual fpecific action being very great in comparison with the attraction of gravitation (as we certainly observe in the action of light), all the phenomena of electricity will be produced without any fensible effect on the phenomena of gravitation, even although neither the electric fluid nor its ally, this ingredient of taugible matter, should not gravitate. But this supposition is by no

means necessary.

Since we call that the natural electrical state of bodies in which they do not affect each other, and the hypothetical powers of the fluid are accommodated to this condition, we may confider any body that has more than its natural quantity as confifting of a quantity of matter faturated with fluid, and a quantity of redundant fluid superadded; and an undercharged body may be confidered as confitting of a quantity of matter superadded. The faturated matter of these two bodies will be totally inactive on another body in its natural state, and will neither attract nor repel it, nor be attracted nor repelled by it; therefore the action of the overcharged body will depend entirely on the redundant fluid; and that of the undercharged body will depend entirely on the redundant matter; therefore we need only confider them as confifting of this redundant fluid or matter, agreeably to what was faid in more vague terms in no 10. and 13. This will free us from the complicated formulæ which would otherwife be necesgible matter of two bodies on each other. The refults will be sufficiently particular for distinguishing the senfible action of bodies in the chief general cases; but in fome particular and important cases, it is absolutely ne-

ceffary to employ every term.

1. Suppose two bodies A and B, containing the General exquantities F' and f' of redundant fluid, it is plain that pression their mutual action is expressed by $F' \times f' + z$, and that (symboliit is a repulsion; for fince every particle of redundant (al) of the fluid in A repels every particle of redundant fluid in B tion. with the force z; and fince F' and f' are the numbers of fuch particles in each, the whole repulfion must be expressed by the product of these numbers.

2. In like manner, two bodies A and B, containing the redundant matter M' and m', will repel each other

with the force M' m' z.

3. And two bodies A and B, one of which A contains the redundant fluid F', and the other B contains the redundant matter m', will attract each other with the force F m' z.

4. It follows from these premifes, that if either of the bodies be in its natural state, they will neither attract nor repel each other; for, in fuch a cafe, one of the factors \hat{F}' , or f', or M', or m', which is necessary for making a product, is wanting. This may be perceived independent of the mathematical formula; for if A contain redundant fluid, and B be in its natural flate, every particle of the redundant fluid in A is as much repelled by the natural fluid in B as it is attracted

by the tangible matter.

The three first propositions agree perfectly with the Seeming known phenomena of electricity; for bodies repel paradox. each other, whether both are positively or both are negatively electrified, and bodies always attract each other when the one is politively and the other negatively electrified. But the fourth cafe feems very inconfistent with the most familiar phenomena. Dr Franklin and all his followers affert, on the contrary, that electrified bodies, whether positive or negative, always attract, and are attracted, by all bodies which are in their natural state of electricity. But it will be clearly shewn presently, that they are mistaken, and that Franklin's theory necessarily supposes the truth of the fourth proposition, otherwise two bodies in their natural state could not be neutral or inactive, as any one may perceive on a very flight examination by the Franklinian principles. It will prefently appear, with the fullest evidence; and, in the mean time, we proceed to explain the action of bodies which are overcharged in fome part, and undercharged in another.

Let the body B (fig. 4.) be overcharged in the part 38 B n, and undercharged in the part B s, and let f' and Action of the the redundant fluid and common matter in those a body has m be the redundant fluid and common matter in those ving the parts; let A be overcharged, and contain the redun-fluid unedant fluid F'; let z and z' express the intensity of ac quably diftion corresponding with the distances of A from the poled. overcharged and undercharged parts of B; the part B n repels A with the force $F'f'\approx$, while the part B s attracts it with the force F'm'z: A will therefore be attracted or repelled by B, according as Fmz' is greater or lefs than F'f'z'; that is, according as m'z'is greater or lefs than f' z. This, again, depends on the proportion of f' to m', and on the proportion of z to z'. The first depends on many external circumstances, which may occasion a greater or less redundanfary for expressing all the actions of the sluid and tan- cy or deficiency of electrical sluid; the second de-

pends entirely on the law of electric attraction and repullion, or the change produced in its intensity by a change of distance. As we are, at present, only aiming at very general notions, it is enough to recollect, that all the electric phenomena, and indeed the general analogy of nature, concur in shewing that the intensity of both forces (attraction and repulsion) decreases by an increase of distance; and to combine this with that circumstance of the hypothesis which states the repulfion to be equal to the attraction at the same distance; therefore both forces vary by the same law, and we have z always greater than z'. The vifible action of B on A (which, by the 3d law of motion, is accompanied by a fimilar action of A on B) may be various, even with one position of B, and will be changed by changing this position.

Cases of fensihle repulfion.

1. We may suppose that B contains, on the whole, its natural quantity, but that part of it is abstracted from Bs, and is crowded into Bn. This is a very common case, as we shall see presently, and it will be expressed in our formula by making f' = m'. In this case, therefore, we have F'f'z greater than F'm'z, because z is greater than z'. A will therefore be repelled by B, and will repel it; and the repullion will be

 $Ff' \times z - z'$.

- Of attraction.

It is evident, that if A be placed on the other fide of B, the appearances will be reverfed, and the bodies will attract each other with the force $F'f' \times z - z'$.

It is also plain, that if A be as much undercharged as we have supposed it overcharged, all the appearances will be reversed; if on the undercharged side of B, it will be repelled; and if on the overcharged fide of B, it will be attracted.

Of Neutrality.

2. If the redundancy and deficiency in the two portions of B be inversely proportional to the forces, so -that F': m' = z': z, we shall have f'z = m z', and m'

 $\frac{f'z}{z'}$. In this case these two actions balance each

other, and A is neither attracted nor repelled when at this precise distance from the overcharged side of B. B may be faid to be NEUTRAL with respect to A, although A and the adjoining fide of B are both overcharged.

Bodies neu-eral at one fide of B, the effect will be very different: For beend are more active cause $m' = \frac{f'z}{z'}$, and m'z' is now changed into m'z, and

f'z into fz', we have the action on $A = F' \times \left(\frac{f'z}{z'}\right)$ -f'z', $= F'f' \times \frac{z^2 - z'^2}{z''}$; that is, A is strongly

In like manner, fr and m' may be so proportioned, that when A, containing redundant fluid, is placed near the undercharged end of s B, it shall neither be attracted nor repelled, B becoming neutral with regard to A at that precise distance. For this purpose m' must be

 $=\frac{Jz'}{z}$. And if A be now placed at the same distance on the other fide of B, it will be repelled with the force $f(x) = \frac{x^2 - x^2}{x}$.

Thus, when the overcharged end is rendered neutral

to an overcharged body, the other end strongly attracts it; and when the undercharged end is rendered neutral to the same body, the overcharged end strongly repels it.

Similar appearances are exhibited when A is under-

charged.

These cases are of frequent occurrence, and are im-

portant, as will appear afterwards.

It is easy now to see what changes will be made on the action of B on A, by changing the proportion of

f' and m'. If m' be made greater than $\frac{f'z}{z'}$, A will be attracted in the fituation where it was formerly neutral; and if m' be made less, A will be repelled, &c. &c.

Therefore, when we observe B to be neutral, or attractive, or repulsive, we must conclude that m' is equal

to fe, or greater or less than it, &c.

We have been thus minute, that the reader may perceive the agreement between this action on a body containing redundant fluid, and the action on the superficial fluid formerly considered in no 21, 22, 23, 24. When these things are attended to, we shall explain, with great eafe, all the curious phenomena of the electrophorus.

There is another circumstance to be attended to here, Neuro which will also explain some electrical appearances that genera feem very puzzling. We limited the inactivity of Blimited to a certain precise distance of the body A. This in-precise

activity required that m' should be $=\frac{fz}{z'}$. If A be formal brought nearer, both z and z' are increased. If they from are both increased in the same proportion, the value of

 $\frac{z}{z'}$ will be the same as before, and the body A will nei. ther be attracted nor repelled at this new distance. But if z increase faster than z', we shall have f z greater than m'z', and A will be repelled; and if z increases more slowly than z', A will be attracted by bringing it nearer. The contrary effects will be observed if A be removed farther from the overcharged end of B. This explains many curious phenomena; and those phenomena become instructive, because they enable us to discover the law of electric action, by shewing us the manner in which it diminishes by a change of distance. Electricians cannot but recollect many instances, in which the motion of the electrometer appeared very capricious. The general fact is, that when an overcharged pith ball is so situated near the overcharged side of the electrophorus as to be neutral, it is repelled when brought nearer, but attracted when removed to a greater diffance. This shews that a increases faster than at when A is brought nearer to B. Now, fince the bodies may be again rendered neutral at a greater distance than before, and the same appearances are still observed, it follows, that the law of action is fuch, that every diminution of distance causes z to increase faster than z'. We shall find this to be valuable information.

Let us, in the last place, inquire into the sensible ef-Action fect on A when it also is partly overcharged and part when ly undercharged. This is a much more complicated ilini case, and is susceptible of great variety of external appearances, according to the degrees of redundancy and out deficiency, and according to the kind of electricity (pofitive or negative) of the ends which front each other.

First, then, let the overcharged end of A (fig. 5.) front the undercharged end of B, they being overcharged in N and n, but undercharged in S and s. Let F and f be the quantity of fluid natural to each; and let F' and f' be the redundancy in N and n, and M' and m' the deficiency in S and s. Moreover, let Z and Z' represent the intensity of actions of a particle in N on a particle in n and s; and let z and z' represent the actions of a particle in S on a particle in n and in s; or, in other words, let Z, Z', z, z', represent the intensity of action between particle and particle, corresponding to the distances Ns, Nn, Ss, Sn.

Proceeding in the fame manner as in the former examples, we easily see, that the action of B on A is = F'm'Z - F'f'Z' - M'm'z + M'f'z'; the attrac-

tions are confidered as positive quantities, having the fign + prefixed to them, and the repulsions are nega-

tive, having the fign -This action will be either attractive or repulsive, according as the fum of the first and last terms of the numerator exceeds or falls short of the sum of the second and third: And the value of each term will be greater or less, according to the quantity of redundant fluid and matter, and also according to the intensity of the electric action. It would require feveral pages to state all those possible varieties. We shall therefore content ourselves at present with stating the simplest case; because a clear conception of this will enable the reader to form a pretty diffinct notion of the other possible cases; and also, because this case is very frequent, and is the most useful for the explanation of phenomena.

We shall suppose, that the redundant part of each body is just as much overcharged as the deficient part is undercharged; fo that F' = M', and f' = m'. In this

case, the formula becomes $\frac{F'f'(Z-Z'-z+z')}{}$ $\mathbf{F}f$

Here we see that the sensible or external effect on A depends entirely on the law of electric action, or the of the variation of its intensity by a change of distance. If the fum of Z and z' exceed the fum of Z' and z, A ates to will be attracted; but if Z + z' be less than Z' + z, A will be repelled. This circumstance suggests to us a very perspicuous method of expressing these actions between particle and particle, fo that the imagination shall have a ready conception of the circumstance which determines the external complicated effect of this inter-This will be obtained by measuring off nal action. from a fixed point of a straight line portions respectively equal to the distances Ns, Nn, Ss, and Sn, between the points of the two bodies A and B, where we suppose the forces of the redundant sluid and redundant matter to be concentrated, and erect ordinates having the proportion of those forces. If the law of action be known, even though very imperfectly, we shall see, with one glance, of which kind the movements or tendencies of the bodies will be. Thus, in fig. 5. drawing the line Cz, take Cp = Ns, Cq = Nn, Cr = Ss, and Ct = Sn, and erect the ordinates P, p, Qq, Rr, and Tt. If the electric action be like all the other attractions and repullions which we are familiarly acquainted with, decreasing with an increase of distance, and decreasing more slowly as the distances are greater, these ordinates will be bounded by a curve PQRTZ, which has its convexity turned toward the axis. We

shall presently get full proof that this is the case here; but we premise this general view of the subject, that we may avoid the more tedious, but more philosophical, process of deducing the nature of the curve from the phenomena now under confideration.

This construction evidently makes the pair of ordi-General nates Pp, Qq, equidiffant with the pair Rr, Tt, character Alfo, Pp, Rr, and Qq, Tt, are equidiffant pairs. It of the scale is no less clear, that the sum of Pp and Tt, exceeds force, the sum of Qq and Rr. For if Cz be bifected in V_q , and V_q be drawn perpendicular to it. and V v be drawn perpendicular to it, cutting the ftraight lines PT and QR in x and y, then xv is the half fum of Pp and Γt , and yv is the half fum of Qq and Rr. Moreover, if Qm and Γn are drawn parallel to the base, we see that Pm exceeds R r; and, in general, that if any pair of equidiftant ordinates are brought nearer to C, their difference increases, and vice versa. Alio, if two pairs of equidifiant ordinates be brought nearer to C, each pair by the fame quantity, the difference of the nearest pair will increase more than the difference of the more remote pair. And this will hold true, although the first of the remote pair should stand between the two ordinates of the first pair. If the reader will take the trouble of confidering these simple consequences with a little attention, he will have a notion of all the effects that are to be expected in the mutual actions of the two bodies, fufficiently precise for our present purpose. We shall give a much more accurate account of these mathematical truths in treating the article MAGNETISM, where precifion is absolutely necessary, and where it will be attended with the greatest success in the explanation of phenomena.

Now let us apply this to our present purpose. First, then, When the overcharged end of A is turned toward the undercharged end of B, A must be attracted; for Pp + Tt is greater than Qq + Rr.

Secondly, This attraction must increase by bringing the bodies nearer; for this will increase the difference between P m and R n.

Thirdly, The attraction will increase by increasing the length either of A or of B (the distance Ns remaining the same); for by increasing the length of A, which is represented by pr or qt, Rr is more diminish. ed than Tt is. In like manner, by increasing B, whose length is represented by pq or rt, we diminish Qq more than Tt.

On the other hand, if the overcharged end of B front Use of this. the overcharged end of A, their mutual action will be picture of F'f'(-Pp+Qq+Rr-Tt),

and A will be repelled, and the repulsion will increase or diminish, by change of distance or magnitude, precifely in the same manner that the attractions did. It is hardly necessary to observe, that all these consequences will refult equally from bringing an apparatus. fimilar to that represented in fig. 3. near to another of the fame kind; and that they will be various according to the position and the redundancy or desciency of the Curious

two parts of each apparatus. If the body B of fig. 5, is not at liberty to approach which toward A, nor to recede from it, and can only turn full from round its centre B, it will arrange itself in a certain the hypodeterminate position with respect to that of A. Forthesis, reexample, if the centre B (fig. 7.) be placed in the line fembling paffing magnetifns.

48. ..

paffing through S and N of the body A, B will arrange itself in the same straight line: for if we forcibly give it another position, such as s B n, N will attract s and repel n, and these actions will concur in putting B into the position s' B n'. S, however, will repel s and attract n; and these forces tend to give the contrary pofition. But S being more remote than N, the former forces will prevail, and B will take the position s' B n'.

If the centre B be placed somewhere on the line AD, drawn through a certain point of the body NAS (which will be determined afterwards), at right angles to NAS, the body B will assume the position n' B s', parallel to NAS, but subcontrary. For if we forcibly give it any other position n Bs, it is plain that N repels n and attracts s, while S attracts n and repels s. These sour forces evidently combine to turn the body round its centre, and cannot balance each other till B assume the position n' B s', where n' is next to S, and s' is next to N.

Form of meridian.

Confe-

If the centre of B have any other fituation, fuch as the electric B', the body will arrange itself in some such position as n' B' s'. It may be demonstrated, that if B be infinitely small, so that the action of the end of A on each of its extremities may be confidered as equal, B will arrange itself in the tangent BT of a curve NBS, fuch that if we draw NB', SB, and from any point 'I' of the tangent draw TE parallel to BN, and TF parallel to B'S, we shall have BE to BF, as the force of S to the force of N. This arrangement of B will be still more remarkable and distinct if N be an overcharged fphere, and S an undercharged one, and both be infulated. We must leave it to the reader's reflection to fee the clianges which will arife from the inequality of the redundancy and deficiency in A or B, or both, and proceed to confider the confequences of the mobility of the electric fluid. These will remove all the difficulty and paradox that appears in some of the foregoing propositions.

Let the body A (fig. 4.) contain redundant fluid, (fundamen and let B be in its natural flate, but let the fluid in A tal) of the be fixed, and that in B perfectly moveable; it is evident mobility of that the redundant fluid in A will repel the moveable the fluid in fluid in B, toward its remote extremity n, and leave it the pores of undercharged in s. The fluid will be rarefied in s, and conflipated in n. We need only confider the mutual actions of the redundant fluid and redundant matter. It is plain that things are now in the situation described in n° 15.: A must be attracted by B, because f' = m', and z is greater than z'. The attractive force is $F'f' \times (z-z')$.

Thus we see that the hypothesis is accommodated to Bodies containing the the phenomena in the case in which it appeared to differ natural fo widely from it. Had the fluid been immoveable, the natural the mutual actions would have fo balanced each other flate, at- that no external effects would have appeared. But track and now the greater vicinity of the redundant matter preare attract-vails, A is attracted by B, and, the actions being all ed by electrified bo-mutual, B is attracted by A, and approaches it. We have supposed that the fluid in A is immoveable;

52 but this was for the lake of greater simplicity. Sup-Andchange pose it moveable. Then, as soon as the uniform distri-the state of bution of the sluid in B is changed, and B becomes undies, which dercharged at s, and overcharged at n, there are forces increases acting on the sluid in A, and tending to change its attraction. flate of distribution. The redundant matter in S attracts the redundant fluid in A more than the more remote redundant fluid in n repels it, because z' is less than z. This tends to constipate the redundant fluid of A in the nearer parts, and render N more redundant, and S less redundant in fluid than before. It is plain, that this must increase their mutual action, without changing its nature. It can be firicily demonstrated, that however small the redundancy in A may be, it can never be rendered deficient in its remote extre. mity by the action of the unequally disposed fluid in B, if the fluid in B be no more nor less than its natural quantity. It is also plain, that this change in the difposition of the fluid in A must increase the similar change in B. It will be still more paressed in s, and condenfed in n; and this will go on in both till all is in equilibrio. When things are in this state, a partiele of fluid in B is in equilibrio by the combined action of several forces. The particle B is propelled toward n by the action of the redundant Ruid in A. But it is urged toward S by the repullion of the redundant fluid on the fide of n, and also by the attraction of the redundant matter on the fide of s; and the repulsion of the redundant fluid in A must be conceived as balancing the united action of those two forces residing in B.

Hence we may conclude, that the denfity of the fluid General in B will increase gradually from s to n. It will be ex-n tion of tremely difficult to obtain any more precise idea of its the force denfity in the different parts of B, even although we of clediti knew the law of action between fingle particles

This must depend very much on the form and dimen body. fions of B; for any individual particle fustains the fensible action of all the redundant fluid and redundant matter in it, fince we suppose it affected by the more remote fluid in A. All that we can fay of it in general is, that the denfity in the vicinity of s is less than the natural density; but in the vicinity of n it is greater; and therefore there must be some point between s and n where the stuid will have its natural density. This point may be called a NEU-TRAL point. We do not mean by this that a particle point. of superficial fluid will neither be attracted nor repelled in this place. This will not always be the cale (although it will never be greatly otherwise); nor will the variation of the denfity in the different parts of B be proportional to the force of A on those parts. Some eminent naturalists have been of this opinion; and, having made experiments in which it appeared to be otherwife, they have rejected the whole theory. But a little reflection will convince the mathematician, that the fum of the internal forces which tend to urge a particle of fluid from its place, and which are balanced by the action of A, are not proportional to the variations of denfity, although they increase and decrease together. We shall take the proper opportunity of explaining those experiments; and will also consider some simple, but important cases, where we think the law of distribution of the fluid afcertained with tolerable precision.

If we suppose, on the other hand, that A is undercharged, the redundant matter in A will attract the moveable fluid in B, and will abstract it from the remote extremity, and crowd it into the adjacent extremity. Moreover, the fluid now becoming redundant in the nearer extremity of B, will act more strongly on the moveable fluid in A than the more remote redundant matter of B; and thus fluid will be propelled toward the remote fide of A, which will become now under-

charged

charged in its nearer side, and less undercharged in its remote fide than if B were taken away. This must increase the inequability of distribution of the sluid in B, and both will be put farther from their natural state; but A will never become overcharged in its remote ex-

Things being in this state, it is plain that A and B will mutually attract each other in the same manner, and with the same force, as when A was as much over-

charged as it is now undercharged. Fricat- Thus, then, we fee how the attraction obtains, whehere is ther A be over or undercharged. A fact which Dr to the Franklin could never explain to his own fatisfaction; nor will it ever be explained confistently with the acof the knowledged principles and observed laws of mechanics by any person who employs elastic atmospheres for this purpose. It is indeed a sufficient objection to the employment of such electric or other atmospheres, that the same extent of attraction and repulsion between the particles of the atmosphere is necessary, as is employed here between the particles of the fluid refiding in the body; and therefore they cease to give any explanation, even although their supposed actions were legitimately deduced from their constitution. This is by no means the case. Let any person examine seriously the modus operandi of the electric atmospheres employed by Lord Mahon (the only person who has written mathematically on the subject), and he will see, that the whole is nothing but figurative language, without any diffinct perception of what is meant by these atmos. pheres, as diffinct from the fluid moveable in the conducting bodies, or any perception how the unequal denfity of these atmospheres protrudes the fluid along the conductor. Besides, it is well known that a conducting wire becomes positive at one end, and negative at the other, by the mere vicinity of an overcharged or undercharged body, and this in an instant, although it be furrounded with fealing wax, or other nonconductors, to any thickness: in this case there can be no atmospheres to operate on the included fluid. To this we may add Dr Franklin's judicious experiment of whirling an electrified ball many times round his head, with great rapidity, by means of a filk line, without any fenfible diminution of its electricity. It is not conceivable that an electric atmosphere could remain attached to the ball; nor could it be inflantaneously formed round the ball, in every point of its motion, so as to be operative the moment he stopped it and tried it; for this would have exhausted or greatly diminished the electricity of the ball; whereas that fagacious philosopher affirms (and any person will find it true), that when the air is dry, he did not observe the electricity more diminished than that of another ball which remained all the while in the same place.

Let the overcharged body A (fig. 6.) be brought y. near the ends of two oblong conductors B and C in their natural state, and lying parallel to each other; the fluid will be propelled toward their remote ends N, n, where it will be condenfed, while it will be rarefied in the ends S and s, adjacent to A. Both will be attracted by A, and will attract it. But the redundant fluid in NB will repel the redundant fluid in nC; and the redundant matter in SB will repel the redundant matter in s C. For this reason the bodies B and C will repel each other, and will separate; but SB attracts

SUPPL. VOL. I. Part II.

nC, and NB attracts s C; and on this account the bodies should approach: but the distances of the attracting parts being greater than those of the repelling parts, the repulsions must prevail, and the bodies must really separate.

It is equally clear that the very same fensible appearance will result from bringing an undercharged body near the ends of B and C, although the internal motions

are just the opposite to the former.

If another body D, electrified in the same way with A, be brought near the opposite ends of B and C, it will prevent or diminish the internal motions, and it should therefore prevent or diminish the external effects.

If another conducting body be brought near to the end s of C that fronts A, it will be affected as C is, and the end f will repel s; but if it be brought near the remote end, as is the case with the body F, it will attract this remote end As the body A, containing more or less than its natural share of electric fluid, affects every other body, while they do not (when out of its neighbourhood) affect each other, it is usually said to be the electrified body, and the others are faid to be electrified by it; and fince these bodies, when perfect conductors, cannot retain their power of exhibiting electrical appearances (fee no 17.), it will be convenient to distinguish this last electrical state by a particular name. We shall call it ELECTRICITY BY POSITION, Or INDU-CED ELECTRICITY. It is induced by position with regard to the permanently electrical body.

We have supposed, in these last propositions, that Consequenthe sluid was perfectly moveable in B, and, at last also, ces of ob-1 in A: but let us examine the consequences of some ob-structions. struction to this motion. Without entering into a minute enquiry on this head, we may state the obstruction as uniform, and fuch that a certain small force is necessary for causing a particle of fluid to get through between two particles of the common matter, just as we conceive to happen in tenacious bodies of uniform tex-

ture (see n° 18.).

It is evident, that when an overcharged body A (fig. 4. or 5.) is brought near fuch an imperfect conductor B, the fluid cannot be fo copiously propelled to the remote extremity n. We may conceive the state of dif-tribution by taking a constant quantity from the intenfities of the force of A at every point of B. This circumstance alone shews us, that there will not be so unequable a distribution of the sluid, and therefore there will not be fuch a strong attraction between imperfect as between perfest condustors. But besides this, we see that an incomparably longer time must elapse before things come to a state of equilibrium. Each particle of fluid employs time to overcome the obstacle to its motion, and it cannot advance till after the succeeding ones, each escaping in its turn, have again come up with the foremost. An important consequence refults from this. The neutral point, where the fluid is of the natural denfity, will not be so far from the other body as it would have been without these obstructions; and this point will be a considerable while of advancing along the imperfect conductor. At the first approach of the overcharged electric, the near extremity of the imperfect conductor becomes a little undercharged, and the neutral point advances from the very extremity a small way, the displaced sluid being crowded a little before it, and giving way by degrees

as its foremost particles get past the obstructions. The motion forward takes place over a considerable extent at the very first; namely, in that part of the conductor where the propelling power of the neighbouring electric is just able to push a particle over the obstruction. As the propulsion goes on, the neutral point must gradually advance, and at last reach a certain distance, determined by the degree of the obstruction. It is plain, that the final accumulation at the remote end of the imperfect conductor will be less than in a perfect conductor, and the neutral point will be nearer to the other end.

17 Irregular diffribution.

There is another remarkable consequence of the obstruction. It must always happen that, at the beginning of the action, the greatest constipation will not be towards the remote extremity, but in a place much nearer to the disturbing cause. Beyond this, the constipation will diminish. As time elapses during this operation, this constipated fluid acts on the fluid beyond it by repulsion, and may do this with sufficient sorce to difplace some of it, and render a part of the impersect conductor deficient, with a small constipation beyond it. This may, in like manner, produce a rarefaction farther on, followed by another condensation; and this may be frequently repeated when the obstruction is very great, and the repulsion of the overcharged body very great also. This can be strictly demonstrated in some very fimple cases, but the demonstration is very tedious: As the result, however, is of the first importance in the theory of electricity, and ferves to explain some of the most abstruse phenomena, we wish the reader to have some stronger ground of confidence than the above bare af fertion. He may observe similar effects of causes precifely fimilar. If we dip the end of a flat ruler into water, and if, after allowing the water to become perfeetly still, we move the ruler gently along in a direction perpendicular to the face, we shall observe a single wave heap up before the ruler, and keep before it, all the rest of the water before it remaining still: but if we do the fame thing in a veffel of clammy fluid, especially if the clammy part is fwimming on the furface of a more perfect fluid, like a cream, we shall observe a series of fuch waves to curl up before the ruler, and form before it in fuccession; and if we have previously spotted the furface of the cream, we shall see that it is not the same individual waves that are pushed before the ruler, but that they are successively formed out of different parts of the furface, and that the particles which, at one time, form the summit of a wave, are, immediately after, at the bottom, &c. In like manner, when a cannon is fired in clear air, at no great distance, we hear a fingle fuap; but, in a thick fog, we hear the fnap both preceded and followed by a quivering noise, resembling the rushing of a fluttering wind, which lasts perhaps half a fecond. A flight reflection on these facts will shew that they are necessary results of the mechanical laws of fuch obstruction.

Several neutral points.

The confequence of this mode of action must be, that an imperfect conductor may have more than one neutral point, and more than one overcharged and undercharged portion, so that its action on distant bodies may be extremely various. The formula of no 28. was accommodated to this case, and will be sound to have very curious results. Another body may be placed in the direction of the axis, and will be attracted

at one diftance, repelled when this diftance is increased, and again attracted when at a still greater distance, &c.

Suppose the obstruction not to be considerable: The immediate operation of the neighbouring overcharged body will be the production of an undercharged part in the adjoining extremity, an overcharged part beyond this, an undercharged portion farther on, &c. In a little while these will shift along the conductor; one after another will disappear at the farther end, and the body will have at last but one neutral point. A greater obstruction will leave the body, finally, with more than one neutral point, and their ultimate number will be greater in proportion as the obstruction to the sluid's

motion is supposed greater.

Now, let the overcharged body, the cause of this un-induced equal distribution, be removed. We have seen, no 17. lectricit that when a body contains its natural quantity of fluid, rendered but unequally distributed, there is a force acting on permane every particle, and tending to reftore the original equable distribution; and that such a force remains as long as there is any inequality in this respect. If, therefore, there be no obstruction, the uniform distribution will take place immediately; for it is well known, that the fpeed with which electricity is propagated is immense. The elasticity, or the attractive and repulsive forces, must be very great indeed when compared with any that we know, except, perhaps, the force which impels the particles of light. The electricity, therefore, of a perfect conductor, that is, its power of acting on other bodies in the same way that an original electric acts on them, must be quite momentary, and cease as soon as the inducing cause is removed. The conductor is electrical merely in consequence of its position. Hence the propriety of our denominations. Nothing material is supposed in this theory to be communicated from the overcharged body: Nay, this theory teaches, that the fenfible electricity of the overcharged body is augmented in some respects; for it becomes more overcharged in the part nearest to the conductor. Indeed it becomes less overcharged on the other end, and will act less forcibly on that side than if the conductor were away. It may be remarked here (it should have been mentioned in no 55.), that when F is presented in the manner shewn in fig. 6. the body B becomes more strongly overcharged at the end remote from A, and more firougly undercharged at the end next to A, than when F is away. The contrary may happen, by prefenting a body in the manner of E. We wish these particulars to be kept in mind. In the mean time, all these circumstances are necessary consequences of the fupposition, that nothing is communicated from A to B or C. The electricity induced on perfect conductors is momentary, requiring the continual presence of a body that is electrified in some way or other.

But the case is quite otherwise in imperfect conductors. When the overcharged, or otherwise electrical body A is removed, the forces which tend to restore the uniform distribution of the sluid immediately operate, and must restore it in part. They cannot, however, do it completely: For when the force which unges any particle from an overcharged to an undercharged part is just in equilibrio with the obstruction, it will remain, just as a number of grains of small shot may lie, uniformly mixed with a mass of clammy sluid, or,

as fuch fluids retain heavy mud, in a state of equable or inequable diffusion. If the resistance arise merely from the inertia of the tangible matter, there is no force fo small but it will in time restore the uniform distribution. But this cannot be the case in solid bodies. Their particles exert lateral forces, by which they maintain themselves in particular situations: these must be overcome by superior forces.

We should therefore expect, that imperfect conductors will retain part of their inequable constitution; and, in consequence of this, their power of affecting other bodies like electrics; that is, their ELECTRICITY. For we must observe (having neglected to do it in the beginning), that the term electricity is as often used to express this power of producing electrical phenomena as it is used for expressing a substance supposed to be the original cause of all these appearances. It is necesfary to keep this diffinction in mind; because there are many phenomena which clearly indicate the transference of this cause, and they must not be confounded with others, where the exhibition of electric phenomena is evidently propagated to a distance. must not always suppose, that when the electric appearances are exhibited in an instant at the far end of a wire 4½ miles long, the same numerical particles of the electric fluid have moved over this space. We must distinguish those cases where this must be granted from those in which it certainly has not happened. Of these there are innumerable instances.

We have now to observe, that by this theory the ductors fingle circumstance of perfect and imperfect conducting necessa- power is sufficient for establishing the whole difference between idio-electrics and non-electrics. The idio-electrics are fusceptible of excitation in various ways, and retain their electricity; and this may be done in any part of them without affecting the rest in any re-markable degree. This cannot be done in perfect conductors, plainly because they are perfect conductors. Any inequality of distribution of the electric fluid, which is all that is necessary for rendering them electric, is immediately destroyed by its uniform diffusion. We can have no direct proof of their incapability of excitation; but if they can be excited, they cannot shew it. We doubt, however, their excitability; because the appearances in the excitation of electrics feem to indicate, that opposite states of two bodies are necessary previous to the appearance of electricity. This is impossible in perfect conductors. By this theory, therefore, perfect conductors are receffarily non-electrics; and non-conductors are necessarily (if excitable) idio electrics.

With respect to the particular phenomena which may be expected on the removal of the original electric; it may just be remarked, that the electric appearances of the imperfect conductor will go off in the contrary order to that of their indication. The accumulation and deficiency will diminish gradually, and the neutral point or points will gradually approach the end which had fronted the original electric. The imperfect conductor will be finally left with one or more neutral points, according to the magnitude of the obstructions, and the force which had been employed in its electrification: And their final state will be so much the more inequable, and confequently they will retain fo much the greater electric powers, as they are less perfect conductors.

The last observation which we shall make on this head at prefent is, that whether electrified by induction, or by friction, or most other modes of excitation, superficithe electrification will be nearly superficial in bodies ally so. which conduct very imperfectly; and bodies which are altogether impervious (if there be any fuch) must have the accumulation or deficiency altogether at their furface. If a glass globe be such a body, it will hardly be possible to electrify it to any depth; and all that we can expect is alternate itrata of overcharged and undercharged glass. If these strata are once formed, they tend greatly to make the body retain its superficial electricity. A superficial ftratum of redundant fluid, tending, by the mutual repulfion of its particles, to escape, is retained by the Aratum of redundant matter immediately below it: And the almost insuperable obstruction prevents the sluid of the stratum beyond this from coming up to supply the vacancy. If we can fall on any contrivance to produce fuch deficient strata within the glass, we shall make it much more retentive, and capable of holding fast a much greater quantity. We have already mentioned fomething of this in no 14. and we recommend the case to the attentive consideration of the reader.

Thus have we given a sketch of the leading doctrines Compariof this elegant theory of Mr Æpinus, all legitimately fon of the deduced from the circumstances assumed in the hypo theory with thesis concerning the mechanical properties of that sub. experistance which he calls the electric fluid. Let us now see mene, with what fuccess this hypothesis may be applied to account for the phenomena. It would have been more philofophical to have arranged the phenomena, and from the comparison to have deduced the hypothesis. But this would have required much more room than can be afforded in a Work like ours.

We prefume, that many of our readers, namely, all fuch as are already conversant with electrical phenomena and with electric experiments, have feen, as we went along, the perfect agreement of the hypothesis with the various phenomena of attraction and repulsion, and all those which are usually classed under the name of electric atmospheres: and we are confident, that when they compare the confequences that should necessarily result from fuch a fluid with the legitimate confequences of the mechanical action of elaftic atmospheres, they will acknowlege the great superiority of this hypothesis in point of fimplicity, perspicuity, and analogy with other general operations of nature. To fuch readers it would not be necessary to state any farther comparison; but there are many who have not yet formed any diftinet systematic view of the appearances called electrical. We do not know any way of giving fuch a view of them as by means of this hypothesis; and we may venture to fay, that it will enable the student of Nature to class them all, with hardly a fingle exception. After which, the hypothesis may be thrown aside by the fastidious philosopher; and the useful classification, and general laws of the electric phenomena, will remain ready foundations for a more perfect theory. For the fake of fuch readers, therefore, we shall take a short review of those general appearances which are accompanied by attractions and repulfions, and compare them with this Æpinian theory.

We shall not at present consider the various modes of excitation, although this theory also affords much in-4 C 2

ilioctrics. Aruction on the subject, but confine ourselves entirely to the facts which are most immediately dependent on it, and should be employed to support or overturn it; and we shall suppose the reader acquainted with most parts of the common apparatus; fuch as electrometers, infulation, &c. We also presume that he knows, that when a small pith ball has been electrified by touching a piece of glafs which has been excited by rubbing with dry flannel, it will repel another body fo electrified; and that balls, which have received their electricity in this manner from fealing wax excited by the same rubber, also repel each other; but that balls, thus electrified by glass, attract those which are electrified by fealing wax.

The following fimple apparatus will ferve for all the experiments which are necessary for establishing the the-

62

Apparatus neceffary

for this

fon.

compari-

1. Two slender glass rode A (fig. 8.), having a brass ball B at the end, about a quarter of an inch in diameter, fufpending a very fmall and delicate pith ball electrometer C.

2. Some electrometers (fig. 9.), confifting of two pieces of rush pith, about four inches long, nicely sufpended, and hanging parallel, and almost in contact with each other. It is proper to have them as smooth as possible, and neatly rounded at the ends, to prevent unnecessary dissipation.

3. Some pith-ball electrometers (fig. 10.), whose threads are of filk, about four inches long, and fome with flaxen threads moistened with a folution of some deliquescent falt, that they may be always in a good

conducting state.

4. Several brass conductors (fig. 11.), each supported They should be about on an infulating stalk and foot. an inch and half or two inches long, and about threefourths of an inch in diameter, with round ends, and well polished, to prevent all diffipation. The foot must be fo narrow as to allow them to touch each other at the ends.

5. 'Iwo balls (fig. 12.), one of glass, and the other of glass coated with sealing wax, each furnished with an infulating handle, the other end of which may be occasionally stuck into a foot, or into the side of a block of wood, which can be flid up or down on a wooden pillar, and fixed at any height. These balls should be about three inches in diameter. They must be excited by rubbing with dry warm flannel.

6. Some little pieces of gilt card (fig. 13.), about two inches long, half an inch broad, and rounded at the ends, and made as fmooth as possible. Each must have a dimple struck in the middle with a polished blunt -ly, an electrometer with very long threads will never point, fo that it will traverse freely like a mariner's needle when fet on a glass point, rounded in the flame of a lamp. More artificial needles may be made of fome light wood, having fmall cork balls at the ends, all gilt and polished, and turning, in like manner, on glass stalks: also some similar needles made of sealing wax, one end of each being black, and the other red.

The mechanical phenomena of electricity may be expressed in a few simple propositions. The most general fact that we know, and from which all the rest may be

deduced, is the following:

If any body A is electrified, by any means whatever, and if another body B is brought into its neighbourhood, the last becomes electrical by position.

Set the brass conductors in a row, touching each other, as represented in fig. 11. by A, B, C; and let a A reutral pith ball electrometer, having filk threads, be fet near body at tracted, bone end of the conductors. Excite one of the globes, cause ren by rubbing it with dry flannel. When this is brought dered ele near the end of the conductor, the pith-ball will ap-trical by proach the other end. But the globe must not be duction. brought fo near as to cause the pith-ball to firike against the other end. On removing the globe, the pith-ball will move off and hang perpendicularly. The fame effect is produced by both globes.

Thus the mere vicinity of the electric renders the conductor electric, and the electricity ceases on removing the globe. This is perfectly conformable to the theory, whether we suppose the fluid to be made redundant or deficient at the remote end of the conductor. If one should ascribe the approach of the pithball to the immediate action of the globe, it is sufficient to observe, that if the ball be suspended near the side of the conductor, it will approach the conductor, shewing that it is affected by the conductor, and not by the

Let the globe be held in the position D (fig. 12.), State of about fix inches from the conductor, and a little above the firibution line of its axis. Take the glass rod (fig. 8.), and bring experime its knob into contact with the under fide of the remote tally, end c of the conductor. The balls of the electrometer will separate, shewing that they are electrified in the same manner, and repel each other. Slide the brass knob along the under fide of the conductors, quite to the end a. The balls will gradually collapse as the knob approaches a point near the middle of the conductors, where they will hang parallel. Passing this point, they will again separate, and most of all when the knob is at a. In this fituation they will deviate toward the globe, and will be directed straight toward it, if it be held too near, or in the direction of the axis. This would disturb the experiment, and must be avoided. These phenomena are conformable to the account given of the disposition of the fluid in the conductor. The electrometer may be confidered as making a part of the conductor; and when its threads hang parallel, it is in its natural state, having its sluid of its natural density. This, however, cannot be firielly true, according to the theory; because the balls of the electrometer must be considered as more remote from the electric, and their electrical state must correspond to a point of the conductor more remote than that where the knob of the electrometer touches it. This will be more remarkably the cafe as the threads are longer. Accordingcollapse. The place of the neutral point cannot be accurately afcertained in this way. Lord Mahon ima-Lord Mahon's determined, that its fituation B was determined (in his area hon's determined) gined, that its fituation B was determined (in his expe-mination riments with a long conductor) to be fuch, that De the neutro was harmonically divided in B and a; and he finds this point not to be agreeable to the refult of an electric atmosphere warrante whose density is inversely proportional to the square of by his exthe distance. But we cannot deduce this from his narration of the experiment. He gives no reason for his felection of the point D, nor tells us the form and dimensions of the electric employed, nor takes into account the action of the fluid in the long conductor. It is evident that no computation can be instituted, even on his Lordship's principles, till all this be done. We

have always found, that the neutral point was farther from the electric, in proportion as the conductor was smaller, and when the electricity was stronger; and that the differences in this respect were so very considerable, that no dependence could be had on this experiment for determining the law of action. It should be so, both according to Lord Mahon's and Mr Æpinus's theory. But to proceed with our examination:

Having touched the end c of the conductor with the knob of the electrometer, bring it away. The balls will continue to repel each other, and they are attracted by any body that is in its natural state. Touch the fame end with the knob of the other electrometer, and bring it also away; the balls of the two electrometers will be found to repel each other: but if one has touched the conductor at c, and the other has touched it at a, the electrometers will strongly attract each other. All this is quite conformable to the theory. If the fluid has been compressed at c, and therefore the balls of that electrometer are overcharged, they must repel each other, and repel any other body electrified in the same way. They must attract and be attracted by any natural body. But the balls of the other electiometer having touched the conductor at a, must be undercharged, and the redundant fluid of the one must attract the redundant matter of the other.

If the conductor has been electrified by the vicinity of excited glass, the electrometer which touched it in the remote end c, will be repelled by a piece of excited glass, but attracted by excited fealing wax. The electrometer which touched the conductor in a will be attracted by excited glass, and repelled by excited fealing wax. The contrary will be observed if the conductor has had its electricity induced on it by the vicinity of the globe covered with fealing wax. This is a complete proof that Mr Dufuy's doctrine of vitreous and refinous electricity is unfounded. Both kinds of electricity are produced in a conducting body, without any material communication, by mere juxta position to a body possessed in the electricity are refinous elec-

tricity.

We have not yet mentioned any reasons which inions dicate which end of the conductor is electrical by ind the redundancy of electric fluid, nor is the reader prepared for feeing their force. It is generally believed, that the remote end of a conductor which is electrified by glass, excited by rubbing it with stannel or amalgamated leather, is electrical by redundancy. No difference has been observed in the attractions and repulfions. But there are other marks of distinction which are constant, and undoubtedly arise from a difference in the mode of action of those mechanical forces. If, while the excited glass globe remains at D, a glass mirror, foiled as usual with tin-leaf, be made to touch the remote end of the conductor, and flowly drawn transversely, so that the conductor draws a line as it were across it-this mirror being laid down with the foiled lide undermost, the dust, which settles on it in the course of a day or two, will be chiefly collected along this line, somewhat in the form of the fibres of a feather. But if the conductor was rendered electrical by the globe covered with fealing-wax, the dust will be collected along this line in little spots like a row of beads. The appearances will be reverfed if the mirror has been passed across the end of the conductor which is nearest to the excited

electric. In short, in whatever way the drawing point has been electrified, if it repel a ball which has touched excited glass, the line will be feathered; but if it attract fuch a ball, the line will be spotted. There are many ways of making this appearance much more remarkable (fee ELECTRICITY, Encycl. Sect. viii. nº 48.) than this; but we have mentioned it on this occasion, because the circumstances which occasion the difference, whatever it is, are the most simple possible. Nothing is communicated; and therefore the effect must arise from the unnatural state of a substance or power residing in the body. If it be a fubstance fui generis, the electric action must arise from a different distribution of this fubstance; from a redundancy and deficiency of it in the different portions of the conductor. Without pretending as yet to fay which is redundant, we shall fuppose, with Dr Franklin, that the electricity of excited glass is so; and we shall use the words redundant and positive to distinguish this electricity from the other. This is merely that we may, on many occasions, confiderably abbreviate language.

The different electrical states of the different por-

The different electrical states of the different portions of the conductor may be seen in another way, which is perhaps more simple and unexceptionable than that already narrated. While the globe remains at D, take the two extreme pieces A and C aside; or, if only two pieces have been used, draw the remote piece farther away. Now remove the excited globe. When we examine A separately, we shall find it wholly negative, or undercharged, strongly repelling a ball electrified by glass. The other piece C exhibits positive electricity, attracting and repelling what A repelled and attracted. If only three pieces of the conductor have been employed, the middle piece B is generally positive; but this

in a very faint degree.

If all the pieces be again joined, they are void of electricity. If, instead of such conductors, a row of metal balls, suspended by filk lines, are employed, one of them may generally be found without any sensible electricity, when separated from the rest, having been the neutral part of the row while united.

These very simple fact, shew, as completely as can be wished, that if the electric phenomena depend on a sluid moveable in the pores of the body, the constitution given it by Mr Æpinus is adequate to the explanation. We may now venture to affert, that every other phenomenon of attraction and repulsion will be found in exact conformity with the legitimate consequences of this constitution of the electric sluid.

That nothing is communicated from the electric will in the inappear still more forcibly by the following experiment: duction of Let a conductor be rendered electrical in the way now electricity described, and touch either extremity of it with the little electrometer, and observe attentively the divergencated. Incey of its threads. Now approach its remote extremi-herent ty with another conducting body, such as a single piece howers are of those conductors, it will be rendered electrical; as may be discovered by a delicate electrometer. Observe carefully whether the electrometer in contact with the first conductor be affected:—it will generally be found to spread its threads wider. It will certainly be thus affected if the other conductor be very long and bulky, or touched by the hand; or if, instead of this second conductor, we approach the first with the extended

palm

į.

paim of the hand. As the second conductor was rendered electrical, fo, undoubtedly, is the hand also: and its electrification has not deprived the first conductor of any of its electric power, but, on the contrary, has increased it. And this augmentation of its power is equally fenfible at both ends: For an electrometer at the other end will also diverge more when the hand is brought near the remote end. This theory explains this in the most satisfactory manner. The first conductor renders the fecond electric, by propelling its fluid to a greater distance. The second conductor now acts on the fluid that is moveable in the first, and causes a greater accumulation in its end which is farthest from the electric; that is, renders it more electric.

Suppose that, instead of employing an excited globe disposition of glass, we had made use of a conducting body, slightly of fluid is overcharged. Thus if we employ the conductor A, overaffected by scharged, to induce electricity on C; this will produce the trified bo. same general effect on our set of conductors. But if we -have previously examined the force of the redundant body, by fuspending a pith-ball near it, and observing its deviation from the perpendicular, we may fometimes be led to think, that it has imparted fomething to the other body. For if the other body and the pith-ball be on opposite sides of the redundant body, the pith ball will fall a little; indicating a diminution of electric force. But this should happen according to the theory; for it was shewn, in no 52. that the constipation in the remote end of the overcharged body will be diminished, and along with this, its action on the pith-ball. We Should find the electricity of the other end, next the conductor, increased, could we find an easy way of examining it; but an electrometer applied there will be too much affected by the conductor.

The same conclusions may be drawn from the following facts: Hang up a rush-pith electrometer. Approach it below with a body slightly electrified. The legs of the electrometer immediately diverge, though attracted by the electrified body. Hold the hand above the electrometer, and they will diverge still more; touch the top of it, and they spread yet farther. Hold the electrified body (very weakly electrified) above the electrometer, so that its legs may diverge a little. Hold the hand above the electrified body; the legs of the

electrometer will come nearer each other.

These appearances are observed whether the electric be positive or negative. We need not take up time in explaining this by the theory, its agreement is so ob-

Electric werticity.

Laftly, on this head, if, in place of a fixed conducneedles po- tor, we use one of the needles of gilt card, fet on its pivot, and if we then approach it with another conducting body, in the manner represented by E and C of fig. 6. we shall observe that end of the needle to avoid the other body; but if we bring them together, in the manner represented by F and B, they will attract each other. The attraction will be greater when the body F is long; and must of all when it communicates with the ground. These phenomena are there. fore in perfect conformity with the theory; but it may sometimes happen that E will attract the end of C that is nearest to A, and E will be electrified positively if A be positive. This seems inconsistent with the theory; and, accordingly, it has been adduced by Volta against Lord Mahon's account of the electrical state of a con-

ductor in a fituation fimilar to that of C. But the theo. ry of Æpinus shews the possibility of this case. When E is very long, or when it is held in the hand, it is rendered much more undercharged than the adjacent part of C; and the fluid in the remoter, but not much remoter, part of C is strongly attracted by the copious redundant matter in the near end of E, and is brought back again, and passes over into E, in the way to be described immediately. The case is rare, and it will not happen at any confiderable distance from the neutral point of C. If, indeed, E touch the near end of C before A is brought near, the approach of A will cause fluid to pass into E immediately, and C will be left undercharged on the whole.

The reader, who is at all conversant with electrical experiments, will be fenfible, that these experiments are delicate, requiring the greatest dryness of air, and every attention to prevent the diffipation of electricity during the performance. This, by changing the state of the conductors and electrometers, will frequently occasion irregularities. The electrometers are most apt to change in this respect, it being scarcely possible to make them perfectly fmooth and free from fharp angles. It may therefore happen, that when the conductors have affected them for fome time, by the action of the diffurbing electric, the removal of this electric will not cause the electrometers to hang perpendicular; they will often be attracted by the conductors, and often repelled; but the intelligent experimenter, aware of these circum-

stances, will know what allowances to make.

The theory obtains a still more complete support phenom from a comparison with fimilar experiments made with of impe imperfect conductors. If, in place of the feries A, B, feet con C, of metalline conductors, we employ cylinders of ductors glass or sealing wax, or even dry wood or marble, and roberate electrometers with filk threads in place of the rush-pithtle the electrometers, we shall find all the appearances to be fuch as the theory enables us to predict. If, for example, we use a fingle cylinder A of glass, we shall find that the neighbourhood of the electric D scarcely induces any electricity on A. The electrometer will hardly exhibit the smallest attraction, and its motions will be almost entirely such as arise from the immediate influence of the electric body D. A cylinder of very dry wood will be more affected by the electric D; and a circumstance of theoretical importance is very distinctly observed, namely, the gradual shifting of the neutral point. It will be found to advance along the cylinder for a very long while, when every circumstance is very favourable, the air very dry, and the wood almost a nonconductor; and its final fituation will be found much nearer to the electric than in the brass conductor. Several instructive experiments of this kind may be found in a treatife published in 1783 by Dr Thomas Milner at Maidstone in Kent, entitled, " Experiments and Observations on Electricity." The author does not profess to advance any new doctrines, but only to exhibit experiments scientifically arranged for forming a system. He supports the Franklinian system as it was generally understood at that time; but is much embarraffed for the explanation of the repulsion of negative electrics. The Æpinian correction of this theory did not offer itself to his mind.

We need not go over the same ground again with fregul imperfect conductors. It is well known that such bo-ties.

d'es are more weakly attracted and repelled; that the balls of an electrometer with linen threads diverge vaftly more when an electrified body is held below it, than if the threads are filken: that fuch electrometers frequently exhibit very capricious appearances from the flow but real progress of the electricity along the threads. These anomalies will be better understood when we explain the diffipation of electricity along im-

perfect conductors.

A very effential deduction from the theory is, that y of the electricity induced on an imperfect conductor must have some permanency. This is fully confirmed by experiment. But the remarkable instances of this parpet, dent. ticular cannot be produced till we be better acquainted with the methods of producing great accumulations of It is enough to observe at present, that a permanent electricity may always be observed at the junction of the conductors with their infulating stalks. The brass conductor A ceases to be electric as soon as the excited globe is removed; but the very top of the glass stalk on which it is supported will sensibly affect a delicate electrometer for a long while after. The following pretty experiment shews this permanency very diflinctly. Set one of the fealing wax needles on its pivot, and place it between two infulated metal spheres of confiderable fize, at fuch a distance from both as not to receive a spark. Electrify these balls moderately, one of them politively, and the other negatively, and keep them thus electrified for fome hours by renewing their electrification. The needle quickly arranges itfelf in the line adjoining the two spheres, just as a magnetic needle will do when placed between two magnets whose diffimilar poles front each other. Any gentle force will derange the needle; but it will vibrate like a magnetic needle, and finally fettle in its former polition. When this has been continued some time, that end of the needle which pointed to the positive globe will be found negative, and the other will be found politive, if examined with an electroscope. And now, if the two globes be removed, this little needle will remain electrical for entire days in dry frosty weather, and its ends will approach any body that is brought near it (taking care not to come too close); and the end which pointed to the positive globe will avoid a piece of rubbed fealing wax, but will approach a piece of rubbed glass; but the other end will be affected in the opposite way. In short, it proves an electric needle with a positive and negative pole.

If two small insulated balls are moderately electrified, and placed about fix inches afunder, this needle, when carried round them, will arrange itself exactly as a magnetic needle does when carried round a magnet of the fame length. If the fame trial be made with the needle of gilt card, it will arrange itself in the same manner that a foft iron needle arranges itself near a magnet, but either end will turn indifferently to either globe.

If a thin glass plate, coated with red fealing wax, be fet on the positive and negative globes, and we sprinkle (from a confiderable height) a fine powder of black fealing wax, and then pat the plate gently with a glass rod fo as to agitate it a little, the particles of wax powder will gradually arrange themselves into curve lines, diverging from the point over one of the globes, and converging to the point over the other, precifely like the curves formed by iron-filings sprinkled on a paper

held over a magnet. Each little rag of wax becomes electrical by polition, acquires two poles, and the politive pole of one attracts the negative pole of another; and they adhere in a certain determinate position, nearly a tangent to the curve, which was mentioned in no 50, and indicates the law of magnetic action. When in this state, if a hot brick be held over the plate till the wax foften a little, the particles of black wax will adhere to the red coating, and give us a permanent specimen of the action.

It is well known that liquid fealing wax is a conductor. The writer of this article filled a glass tube with powdered fealing wax, and melted it, and then ex. posed it, in its melted state, to the influence of a positive and a negative globe, hoping to make a powerful and permanent electric needle, which should have two poles, and exhibit a fet of phenomena resembling those of magnetism. Accordingly he, in some measure, succeeded, by keeping the globes continually electrified for feveral hours, till the wax was quite cold. It had two diffinct poles, and preferved this property, even though plunged in water, and while immerfed in the water; but he was greatly disappointed as to the degree of its electricity. It just affected a sensible electrometer at the diffance of fix inches from either pole. It was confiderably stronger than if it had not been melted during the impregnation, but by no means in the degree that he expected. It retained some electricity for about fix weeks, although lying neglected among conducting bodies. After its power seemed quite extinct, he was melting it again in order to renew it. Some light fibrous things chanced to be near it. While it was foftening, it became very fenfibly electrical, caufing these fibres to bend towards it, and even to cling to the tube. We shall see by and bye, that he was mistaken in expecting more remarkable appearances, and that the theory, when properly applied, does not promife them. Having thus established (as we think) this theory on fufficient foundations for making it a very perspicuous way of explaining the phenomena of induced electricity, we proceed to compare it with the fecond general ? fact in electricity.

PROP. II. When an infulated body B is brought Electricity. very near an electrified body A, a spark is observed to by commupals between them, accompanied with a noise (which nication we shall call the electric SNAP), and B is now electrified permanently, and the electricity of A is dimi-

Although this be one of the most familiar facts in electricity, it will be proper to consider its attending . circumstances in a way that connects it with what we have now learned concerning electricity by position.

Let the infulated body A (fig. 14.) be furnished with a cork ball, hanging by a filk thread from a glass stalk connected with A; let B be fitted up in the same manner; let A be electrified weakly, and its degree of electricity be estimated by the inclination of the ball towards A: fince B is not electrified, its electrometer will hang perpendicular; but when it approaches A (keeping the electrometers on the remote fides of both), its electrometer will approach it, and the electrometer of A will gradually approach the perpendicular. When the bodies are brought very near, a spark is seen between them; and, at that inflant, the electrometer of

B comes

B comes much nearer to it, and that of A drops farther from it. If they be now separated, their electrometers will retain their new positions with very little change, and B will now manifest the same kind of electricity

Such is the appearance when A has been but weakly electrified. Bringing B near A, the fluid in B is drawn to the remote fide, if A be overcharged, or drawn to the side nearest to A, if A has been undercharged. acts on its electrometer in confequence of the change made in the disposition of its fluid. The electrometer is attracted. In the mean time, the change made in the disposition of the fluid in B affects the moveable fluid in A. If A was overcharged, the adjacent fide of B becomes undercharged, and its redundant matter, attracting the fluid in A, condenses it in the adjacent fide, abstracting part of the redundant sluid from that fide which is next to the pith-ball. Then the joint action of the whole redundant fluid in A on the pith-ball

Must hap-

As there is now an attraction in the redundant fluid pen abrupt-in A for the redundant matter on the adjacent fide of B, it is reasonable to suppose, that when this attraction, joined to the repulsion of the redundant fluid behind it, is able to overcome the attraction which connects it with the superficial particles of the matter, it will then escape and fly into B: but this will not happen gradually, but at once, as foon as the expelling force has arisen to a very considerable intensity. We cannot fay what is the precise augmentation that is neceffary; but we can clearly fee, that however great the attraction for the adjoining particles may be, while the particle is furrounded by them on all fides, it will yield to the smallest inequality of force, because the particles before it attract as much as those behind it; but when it is just about to quit the last or superficial particles of A, a ranch greater force is now necessary. It can be strictly demonstrated, that when the mutual tendency is inversely as the square of the distance, the action of a particle placed immediately without a sphere of such matter is double of its action when fituated in the very furface *. A faltus of this kind must obtain whatever be the law of electric attraction. We shall see other causes also which should prevent the escape of redundant fluid, and also its admission, till the impelling force is encreased in a certain abrupt degree.

These observations must suffice at present to explain the defultory nature of this transference, if there be really a transference. That this has happened, may be confidently inferred from the sudden diminution of the electricity of A, indicated by the fueden fall of its electrometer; but it is more expressly established, that there has been a transference by the change produced on B. It is now permanently electrified, and its electricity is of the same kind with that of A, positive or negative according as A is positive or negative. And now we are enabled to explain the third general fact in

electricity.

73 Emparted e

bert, T. I.

257.

PROP. III. When a body has imparted electricity to another, it constantly repels it, unless that other has afterwards imparted all its electricity to other bodies. This fact, from which there is no exception, is an immediate consequence of the theory. Before the transference supposed by it, B was in its natural state; after the transference, both bodies contain redundant fluid. or redundant matter; therefore they mult mutually

We may now take another form of the experiment, which will be much more convincing and instructive. Let A be electrified positively, or by redundancy, and let its electrometer be attached to it by a conducting stalk, and have a flaxen thread; let this be the case also with the electrometer of B; then the appearances should happen in the following order: When A is made to approach B, the electrometer of B must gradually rife, diverging from B; because the sluid condensed on the fide remote from A, and in the electrometer, will act more strongly on it than the deferted matter on the other fide of B; and when the sudden transference is made, and B is wholly overcharged, its electrometer will immedi. ely rife much higher, and must remain at that height, nearly, when A is removed. On the other hand, the electrometer attached to the remote fide of A must descend, by reason of the change made in the disposition of the fluid in A by the induced electrical state of B: and when a considerable portion of the redundant fluid in A paffes into B, the electrometer of A must fuddenly fink much lower, and remain in that state when B is removed.

Many circumstances of this phenomenon corroborate Transferour belief of a real transference of matter. The cause ence of a of electric action refided formerly in A alone; it now pecular refides also in B. The larger that B is, the greater is highly prothe diminution of A's electric power, and the fmaller bable. is the power acquired by B. It perfectly refembles, in this respect, the communication of faltness, sweetness, &c. by mixing a folution of falt or fugar with different quantities of water; and the evidence of a transference of a substance, the cause of electric attractions and repulsions, is at least as cogent as the evidence of the transference of heat, when we mix hot water with a quantity of cold, or when a hot folid body is applied to the fide of a cold one. We also see so many chemical and other changes produced by this communication of electricity, that we can hardly refuse admitting that fome material substance passes from one body to another, and, in its new lituation, exerts its attractions and repulfions, and produces all their effects.

We may deduce the following corollaries; all of which are exactly conformable to the phenomena, ferving still more to confirm the justness of the theory.

1. A certain quantity of what possesses these powers Degrees 0 of attraction and repulsion is necessary for giving a de-vivacty termined vivacity to the appearances. Another spark proportion must pass between the bodies, only if they be brought quantity fill nearer, and their electrometers must rife and fall imparted still farther. For by the first transference of electric suid into B, the expelling power of A is diminished, and the fuperior attraction of the redundant matter in the adjacent fide of B is also counteracted by the repulsion of the fluid which has entered into it; therefore no more will follow unless these forces be encreased, at least to their former degree. When this addition has been made to B, and this abstraction from A, their respective electrometers must be affected. All this is in perfect conformity to experience.

2. All the phenomena of communicated electricity Communicated electricity cation not must be more remarkable in proportion to the con-remarkable ducting power of the bodies. A very imperfect con-in conduc-

ductor, tors.

ductor, such as glass or fealing wax, will impart or receive fluid only between the very nearest parts; whereas a metalline body is instantly affected through its whole extent. This deduction is perfectly agreeable to the whole train of electric experiments. The finger receives a strong spark from a large metalline electrified body, which discharges every part of it of a portion of its electricity. But an excited globe, which shews, by its action on a distant body, as great a degree of electricity, will give only a very fmall spark; and it is found not to be affected at any confiderable distance from the point of its furface from which the transference was made. The whole electricity of a perfect conductor is discharged by touching it; but a nonconductor will successively give sparks, if touched in many different parts; and it may be feen by a nice electrometer, that each contact takes away the electricity only from a very fmall space round it: and it is further highly deferving of notice, that fome time after a spark has been obtained from a particular fpot of the electric, a fecond spark may be obtained from it, the electricity of the neighbouring parts having been gradually diffused through it

3. If an electrified conducting body touch any thing communicating with the ground by perfect conductors, ric all its electricity must difappear, and none can appear in the body touched by it; for the mass of the earth bears fuch an unmeafurable proportion to that of the greatest body that we can electrify, that when the redundancy or deficiency is divided between them, it must

be imperceptible in both.

Hence the necessity of infulation, as it is called, or the furrounding by non-conductors every body which we would have exhibit electric appearances. We must refer the reader to the article ELECTRICITY in the Encycl. for all the observations on this head, and the reafons of preference given to certain fubstances to be employed for infulating fupports. But we must consider, in its proper place, the manner in which the electric fluid is diffipated by imperfectly infulating fubstances; a subject intimately connected with the theory.

4. Any unelectrified body will be first attracted by an electrified body, will touch it, and will then be rend pelled. The neutral body is rendered electrical by induction. It is, in consequence of this, attracted, comes near enough to receive a spark, or even touches it, and is then electrified by communication; and, in confequence of this, it is repelled. This is confirmed by an endless train of experiments. It was first taken notice of (we think) by Sir Ifaac Newton. Otho Guericke, a gentleman of Magdeburgh, to whom we owe the air pump, mentions many inflances of the repulsion, but did not observe that it was an univerfal law. Newton was fo struck with it as to engage in a confiderable train of experiments in the early part of his life, while meditating on the power of gravity; but even his fagacious mind did not observe the whole process of nature in his experiments. He observed, that the light bodies which rofe and adhered to the rubbed plate of glass were soon after repelled by it; but did not obferve, that the same piece would again rife to the glass atmosphere, even if those atmospheres could effect the after it had touched the table. This fact is now the observed motions of the electrometer in consistency foundation of many experiments, which the itinerant electricians vie with each other in rendering very amu- fubflitute millions of attractions or repulsions in place fing. We may render them instructive. Take away of one. We must observe, however, that the motions SUPPL. VOL. I. Part II.

the middle conductor B (fig. 11.), and hang in its place a cork ball by a long filk thread. As foon as the electric body D is brought near to A, the ball is attracted by its remote end, comes into contact, is repelled by it, and attracted by the adjacent end of C, touches it, is faintly repelled by it, and again attracted by A; and the operation is repeated feveral times. When all has ceased, remove C, and also the electric D. C is found to have the fame electricity with D, and A has the opposite electricity. The process is too obvious to need any detailed application of the theory. The cork ball was the carrier of fluid from A to C if D was electric by redundancy, or from C to A if D was undercharged. If initead of removing C when the vibrations of the ball have ceased, we bring D a little nearer, they will be renewed and, after some time, will again cease. The reason is plain. The carrier ball had brought the conductor A into a state of equilibrium with the action of D. But this action is now increafed, and the effects are renewed. If we now remove D, the ball will vibrate between A and C with great rapidity for a confiderable time before the vibrations come to an end; and we shall find their number to be the fame as before. The cause of this is also obvious from the theory. We may suppose A to be negative, and C positive. One of them will attract the ball into contact, and will repel it, having put it into an electric state opposite to that of the other conductor. It now becomes a carrier of fluid from the politive to the negative conductor, till it nearly restore both to their primitive state of neutrality.

There is frequently a feeming capirciousness in those Irregulariattractions and repulfions. A pith ball, or a down featies frequent ther, hung by filk, will cling to the conductor, or other- Why. wise electrified body, and will not fly off again, at least for a long while. This only happens when those bodies are fo dry as to be almost non-conductors. They acquire a politive and negative pole, like an iron nail adhering to a magnet, and are not repelled till they become almost wholly positive or negative. It never happens with conducting light bodies.

5. It should follow from the theory, that the electric Electric acattractions and repulfions will not be prevented by the tion, like intervention of non-conducting fubttances in their neu-gravitation, tral state. Accordingly, it is a fact that their neu-is not hintral state. Accordingly, it is a fact, that the interpo-dered by fition of a thin pane of glafs, let it be ever so extensive, the interdoes not hinder the electrometer from being affected polition of Alfo, if an infulated electric be covered with a glass non-con-bell, an electrometer on the outside will be of Sand authors. bell, an electrometer on the outfide will be affected. Nay, a metal ball, covered to any thickness with fealing wax, when electrified, will affect an electrometer in the fame way as when naked. We cannot fee how thefe facts can be explained by the action of electric atmofpheres. It is indeed faid, that the atmosphere on one fide of the glass produces an atmosphere on the other; but we have no explanation of this production. If the interposed plate be a non-conductor, how does the one atmosphere produce the other? It must produce this effect by acting at a distance on the particles which are to form this atmosphere. Of what use, then, is the with the laws of mechanics? The atmospheres only

81

lectricity

of the electrometer are modified, and fometimes greatly changed, by the interposed non-conducting plate; but this is owing to the electricity induced on the plate. If the electric is positive, the adjacent surface of the plate becomes faintly negative, and the fide next the electrometer flightly positive. This affects the electrometer even more than the more remote electric does. That this is the cause of the difference between the flate of the electrometer when the plate is there and when it is removed, will appear plainly by breathing gently on the glass plate to damp it, and give it a small conducting power. This will make some change in the position of the electrometer. Continue this more and more, till the plate will no longer infulate. The changes produced on the electrometer's position will form a regular series, till it is seen to assume the very position which it would have taken had the plate been brass. Then, confidering those changes in a contrary order, and supposing the series continued a little farther, we shall always find that it leads to the position which it would have taken when no plate whatever is interposed. We confider this as an important fact, shewing that the electric action is fimilar to gravitation, and that there is no more occasion for the intervention of an atmosphere for explaining the phenomena of electricity than for explaining those of gravitation

6. Since non-electrics are conductors, and fince electrics may be excited by friction with a non electric, it folex- lows, that if this non-electric be infulated, and separated out pear from the electric, it will exhibit figns of electricity; but when they are together, there must not appear any marks of it, however strong the excitation may be. We do not pretend to comprehend diffinctly the manner in which friction, or the other modes of excitation, operate in changing the connection between the particles of the fluid and those of the tangible matter; nor is this explained in any electric theory that we know: but if we are fatisfied with the evidences which we have for the existence of a substance, whose presence or absence is the cause of the electric phenomena, we must grant that its usual connection with the tangible matter of bodies is changed in the act of excitation, by friction, or by any other means. In the case of friction producing positive electricity on the surface of the electric, we must suppose that the act of friction causes one body to emit or absorb the fluid more copiously than the other, or perhaps the one to emit, and the other to absorb. Which ever is the case, the adjoining surfaces must be in opposite states, and the one must be as much overcharged as the other is undercharged. When the bodies (which we may suppose to have the form of plates) are joined, and the one exactly covers the other, the affemblage must be inactive; for a particle of moveable fluid, fituated anywhere on the fide of the overcharged plate, will be as much attracted by the undercharged surface of the remote plate as it is repelled by the overcharged furface of the near plate. The furfaces are equal, and equally electric, and act on either fide with equal intenfity; and they are coincident. Therefore their actions balance. The action is expreffed by the formula of n° 43; namely, F' m' $\times \overline{z-z'}$; and z = z' is = 0, by reason of the equal distances of these surfaces from the particle of exterior sluid.

But let the plates be separated. Part, and probably the greatest part, of the redundant fluid on one of ry, and that the change made in the electric state of the

the rubbed furfaces will fly back to the other, being urged both by the attraction of the redundant matter and the repulsion of its own particles. But the electric, being electric because, and only because, it is a non conductor, must retain some, or will remain deprived of some, in a stratum a little within the surface. The two plates must therefore be left in opposite states, and the conducting, or non electric plate, if insulated before separation, must now exhibit electric action.

All this is exactly agreeable to fact. We also know, that electrics may be excited by rubbing on each other; and if of equal extent, and equally rubbed, they exhibit no electric powers while joined together; but when parted, they are always in opposite states. The same thing happens when fulphur is melted in a metal dish, or when Newton's metal is melted in a glass dish. While joined, they are most perfectly neutral; but manifest very strong opposite electricities when they are separated. This completely disappears when they are joined again, and reappears on their separation, even after being kept for months or years in favourable circumstances. We have observed the plates of tale, and other laminated fossils, exhibit very vivid electricity when split

Attention to these particulars enables us to construct Principles machines for quickly exciting vivid electricity on the of the con furface of bodies, and for afterwards exhibiting it with firedion continued dispatch. The whirling globe, cylinder, or mathines. plate, first employed by Mr Hauksbee, for the solitary purpose of examining the electricity of the globe, was most ingeniously converted by Hausen, a German professor, into a rapid collector and dispenser of electricity to other bodies, by placing an infulated prime conductor close to that part of the surface of the globe which had been excited by friction. Did our limits give us room, we should gladly enlarge on this subject, which is full of most curious particulars, highly meriting the attention of the philosopher. But it might eafily occupy a whole volume; and we have still before us the most interesting parts of the mechanical department of electricity, and shall hardly find room for what is effentially requifite for a clear and useful comprehenfion of it. We must, therefore, request our readers to have recourse to the original authors, who have considered the excitation by friction minutely. And we particularly recommend the very careful perufal of Beccaria's Differtations on it, comparing the phenomena, in every step, with this theory of Æpinus. Much valuable information is also obtained from Mr Nicholson's Observations, of which an abstract is given in the article ELECTRICITY Encycl. Britan. The Æpinian theory will be found to connect many things, which, to an ordinary reader, must appear solitary and accidental.

Seeing that this very simple hypothesis of Æpinus Evidence fo perfectly coincides in its legitimate consequences with of the m all the general phenomena of attraction and repulsion, the electric the clean and not only with those that are simple, but even such fluid. as are compounded of many others—we may liften, without the imputation of levity, to the other evidences which may be offered for the materiality and mobility of the cause of those mechanical phenomena. Such evidences are very numerous, and very persuasive. We have faid, that the transference of electricity is defulto-

communicating bodies is always confiderable. It appears to keep fome fettled ratio to the whole electric power of the body. When the form of the parts where the communication takes place, and other circumstances, remain the same, the transference increases with the fize of the bodies; and all the phenomena are more vivid in proportion. When the conductor is very large, the spark is very bright, and the snap very loud.

1. This fnap alone indicates some material agent. It is occasioned by a sonorous undulation of the air, or of fome elastic fluid, which suddenly expands, and as suddenly collapses again. But such is the rapidity of the undulation, that when it is made in close veffels it does not exist long enough, in a very expanded state, to affect the column of water, supported in a tube by the elasticity of the air, for the purpose of a delicate thermometer or barometer; just as a musket ball will pass through a loofe hanging theet of paper without caufing any fensible agitation.

2. The spark is accompanied by intense heat, which will kindle inflammable bodies, will melt, explode, and

calcine metals.

3. The spark produces some very remarkable chemical effects. It calcines metals even under water or oil; it renders Bolognan phosphorus luminous: It decomposes water, and makes new compositions and decompolitions of many gaziform fluids; it affects vegetable colours; it blackens the calces of bifmuth, lead, tin, luna cornea; it communicates a very peculiar smell to the air of a room, which is distinct from all others; and in the calcination of metals, it changes remarkably the fmells with which this operation is usually accompanied: it affects the tongue with an acidulous talte: it agitates the nervous fystem .- When we compare these appearances with fimilar chemical and phyfiological phenomena, which naturalists never hefitate in ascribing to the action of material fubflances, transferable from one body, or one state of combination, to another, we can fee no greater reason for hesitating in ascribing the electric phenomena to the action of a material substance; which we may call a fluid, on account of its connected mobility, and the electric fluid, on account of its diffinguishing effects. We are well aware, that these evidences do not amount to demonstration; and that it is possible that the electric phenomena, as well as many chemical changes, may refult from the mere difference of arrangement, or polition, of the ultimate particles of bodies, and may be confidered as the refult of a change of modes, and not of things But in the inflances we have mentioned, this is extremely improbable.

We therefore venture to assume the existence of this substance, which philosophers have called the electric fluid, as a proposition abundantly demonstrated; and to affirm, on the authority of all the above-mentioned facts, that its mechanical character is fuch as is expref-

sed in Mr Æpinus's hypothesis.

We proceed, therefore, to explain the most interesting phenomena of electricity from these principles.

We have feen that, in a perfect conductor, in its natural state, the electric sluid is uniformly distributed, Pis on and cannot remain in any other condition. We are particularly interested to know how it is distributed in an overcharged or undercharged body, and how this is affected by the circumambient non-conducting air. It

is evident that much depends on this. The tendency to escape, and, particularly, the tendency to transference from one body to another, must be greatest where the sluid is most constipated. We know that it tends remarkably to diffipate from all protuberances, edges, and long bodies, and that it is impossible to confine it in a body having very acute far-projecting points; and, what is more paradoxical, it is hardly possible to prevent its entering into a body furnished with a sharp point. The smallest reflection must suggest to our imagination, that a perfectly moveable fluid, whose particles mutually repel, even at confiderable distances, and which is confined in a veffel from which it cannot escape, must be compressed against the sides of the vessel, and be denser there than in the middle of the vessel. But in what proportion its denfity will diminish as we recede from the walls of the veffel, must depend on the change of electric repulsion by an increase of distance. The intensity varies in the proportion of some function of the distance, and may be expressed by the ordinates of a curve, on whose axis the distances are measured. But we are ignorant of this function. We must there- Process for

fore endeavour to discover it, by observing a proper so discovering lution of phenomena. Having made some approxima-this law. tion to this discovery, such as shall give rise to a probable conjecture concerning the function which expresses the intensity of electric repulsion, mathematics will then enable us to fay how the fluid must be distributed (at least in some simple and instructive cases) in a perfectly conducting body furrounded by the air, and what will be its action on another body. Thus we shall obtain oftensible results, which we can compare with experiments. The writer of this article made many experiments with this view above 30 years ago, and flatters himself that he has not been unsuccessful in his attempts. These were conducted in the most obvious and fimple manner, fuggested by the reasonings of Mr Æ: pinus; and it was with fingular pleafure that, fome years after, he perused the excellent differtation of Mr Cavendish in the Philosophical Transactions, vol. 61. where he obtained a much fuller conviction of the truth of the conclusion which he had drawn, in a ruder way, from more familiar appearances. Mr Cavendish has, with fingular fagacity and address, employed his mathematical knowledge in a way that opened the road to a much farther and more scientific prosecution of the discovery, if it can be called by that name. After this, Mr Coulomb, a distinguished member of the French academy of sciences, engaged in the same refearch in a way still more refined; and supported his conclusions by some of the most valuable experiments that have been offered to the public. We shall now give a very brief account of this argument: and have premifed these historical remarks; because the writer, although he had established the general conclusion, and had read an account of his investigation in a public society in 1769, in which it was applied to the most remarkable facts then known in electricity, has no claim to the more elaborate proofs of the same doctrine, which is given in some of the following paragraphs. These are but an application of Mr Cavendish's more cautious and general mathema. tical procedure, to the function which the writer apprehends to be fufficiently established by observation.

The most unexceptionable experiments with which we can begin, feem to be the repultions observable be-

4D2

tween two small spheres. Whatever be the law of diftribution of the particles in a sphere, the general action of its particles on the particles of another sphere will follow a law which will not differ much from the law of action between two particles, if the diameters of the fpheres be fmall in proportion to their distance from each other. The investigation was therefore begun with them. But the subject required an electrometer fusceptible of comparison with others, and that could exhibit absolute measures. The one employed was made in the following manner; and we give it to the public as a valuable philosophical instrument.

Comparameter.

Fig. 15. represents the electrometer in front. A is ble electro- a polished brass ball, 4th of an inch in diameter. It is fixed on the point of a needle three inches long, as slender as can be had of that length. The other end of the needle passes through a ball of amber or glass, or other firm non-conducting substance, about half or three-fourths of an inch in diameter; but the end must not reach quite to the furface, although the ball is completely perforated. From this ball rifes a slender glass rod FEL, three inches long from F to E, where it bends at right angles, and is continued on to L, immediately over the centre of the ball A. At I, is fixed a piece of amber C, formed into two parallel cheeks, between which hangs the flalk DCB of the electrometer. This is formed by dipping a ftrong and dry filk thread, or fine cord, in melted fealing wax, and holding it perpendicular till it remain covered with a thin coating, and be fully penetrated by it. It must be kept extended, that it may be very straight; and it must be rendered smooth, by holding it before a clear fire. This stalk is fastened into a small cube of amber, perforated on purpose, and having fine holes drilled in two of its opposite fides. The cheeks of the piece C are wide enough to allow this cube to move freely between them, round two fine pins, which are thrust thro' the holes in the cheeks, and reach about half way to the stalk. The lower part of the stalk is about three inches long, and terminates in a gilt and burnished corkball (or made of thin metal), a quarter of an inch in diameter. The upper part CD is of the fame length, and passes through (with some friction) a small corkball. This part of the instrument is so proportioned, that when FE is perpendicular to the horizon, and DCB hangs freely, the balls B and A just touch each other. Fig. 16. gives a fide perspective view of the instrument. The ball F is fixed on the end of the glass rod FI, which passes perpendicularly through the centre of a graduated circle GHO, and has a knob handle of boxwood on the farther end I. This glass rod turns stiffly, but smoothly, in the head of the pillar HK, &c. and has an index NH, which turns round it. This index is fet parallel to the line LA, drawn through the centre of the fixed ball of the electrometer. The circle is divided into 360 degrees, and o is placed uppermoft, and 90 on the right hand. Thus the index will point out the angle which LA makes with the vertical. It will be convenient to have another index, turning stiffly on the same axis, and extending a good way beyond the circle.

This instrument is used in the following manner: A connection is made with the body whose electricity is to be examined, by sticking the point of the connecting wire into the hole at F, till it touch the end of the needle; or, if we would merely electrify the balls A and B, and then leave them infulated, we have only to touch one of them with an electrified body. Now, take hold of the handle I, and turn it to the right till the index reach 90. In this position, the line LA is horizontal, and so is CB; and the moveable ball B is resting on A, and is carried by it. Now electrify the balls, and gently turn the handle backwards, bringing the index back toward o, &c. noticing carefully the two balls. It will happen that, in fome particular pofition of the index, they will be observed to separate. Bring them together again, and again cause them to separate, till the exact position at separation is ascertained. This will shew their repullive force in contact, or at the diffence of their centres, equal to the fum of their radii. Having determined this point, turn the instrument still more toward the vertical position. The balls will now separate more and more. Let an affiftant turn the long index fo as to make it parallel to the stalk of the electrometer, by making the one hide the other from his view. 'I'he mathematical reader will fee that this electrometer has the properties afcribed to it. It will give absolute measures: for by poizing the stalk, by laying some grains weight on the cork-ball I), till it becomes horizontal and perfectly balanced, and computing for the proportional lengths of BC and DC, we know exactly the number of grains with which the balls must repel each other (when the stalk is in a horizontal position), in order merely to separate. Then a very fimple computation will tell us the grains of repulfion when they separate in any oblique position of the stalk; and another computation, by the resolution of forces, will shew us the repulsion exerted between them when AL is oblique, and BC makes any given angle with it. All this is too obvious to need any farther explanation. The reason for giving the connection between A and C fuch a circuitous form, was to avoid all action between the fixed and the moveable part of the electrometer, except what is exerted between the two balls A and B. The needle AF, indeed, may act a little, and might have been avoided, by making the horizontal axis FI to join with A: but as it was wanted to make the instrument of more general use, and frequently to connect it with an electrical machine, a battery, or a large body, no mode of connection offered itfelf which would not have been more faulty in this respect. The neatest and most compendious form would have been to attach the axis FI to C, and to make CA and CB stiff metalline wires, in the same manner as Mr Brookes's electrometer is made. But as the whole of their lengths would have acted, this construction would have been very improper in the investiga-tion of the law of electric repulsion. As it now stands, we imagine that it has confiderable advantages over Mr Brookes's construction; and also over Mr De Luc's incomparable electrometer, described in his Essays on Meteorology. It has even advantages over Mr Coulomb's incomparably more delicate electrometer, which is fenfible, and can measure repulsions which do not exceed the 50,000 of a grain; for the instrument which we have described will measure the attractions of the oppofitely electrified bodies; a thing which Mr Coulomb could not do without a great circuit of experiments. For inftead of making the ball B above A, by inclining the inftrument to the right hand, we may incline it to

the left; and then, by electrifying one of the balls pofitively, and the other negatively, when at a great distance from each other, their mutual attraction will cause them to approach; CB will deviate from the vertical toward A; and we can compute the force by means of this deviation.

We must remind the person who would make observations with this instrument, that every part of it must be fecured against diffipation as much as possible, by varnishing all its parts, by having all angles, points, and roughnesses removed, and by choosing a dry state of the air, and a warm room; and, because it is impossible to prevent diffipation altogether, we must make a previous course of experiments, in a variety of circumstances, in order to determine the diminution per minute corresponding to the circumstances of the experiments that are to be made with further views.

We trust that the reader will accept of this particular account of an instrument which promites to be of confiderable fervice to the curious naturalift; and we now proceed with an account of the conclusions which have been drawn from observations made with it.

Here we could give a particular narration of some of the experiments, and the computations made from them; but we omit this, because it is really unnecessary. It fuffices to fay, that the writer has made many hundreds, with different instruments, of different fizes, some of them with balls of an inch diameter, and radii of 18 inches. Their coincidence with each other was far beyoud his expectation, and he has not one in his notes which deviate from the medium 1 of the whole force, and but few that have deviated i. The deviations were as frequently in excess as in defect. His custom was to measure all the forces by a linear scale, and express them by straight lines crected as ordinates to a base, on which he set off the distances from a fixed point; he then drew the most regular curve that he could through the fummits of these ordinates. This method shews, in the most palpable manner, the coincidence or irregularity of the experiments.

I'he refult of the whole was, that the mutual repulelec. fion of two spheres, electrified positively or negatively, re- was very nearly in the inverse proportion of the squares ha of the distances of their centres, or rather in a propor-

tion fomewhat greater, approaching to 2,06. No difference was observed, although one of the spheres was much larger than the other; and this circumstance

enables us to make a confiderable improvement on the electrometer. Let the ball A be made an inch in diameter, while B is but \$\frac{1}{4}\$ of an inch. This greatly diminishes the proportion of the irregular actions of the rest of the apparatus to the whole force, and also diminishes the diffipation when the general intensity is the same.

When the experiments were repeated with balls hag ving opposite electricities, and which therefore attracame ted each other, the refults were not altogether fo regular, and a few irregularities amounted to to of the whole; but thefe anomalies were as often on one fide of the medium as on the other. This feries of experiments gave a refult which deviated as little as the former (or rather less) from the inverse duplicate ratio of the distances; but the deviation was in defect as the other was in excess.

We therefore think that it may be concluded, that the action between two spheres is exactly in the inverse

duplicate ratio of the distance of their centres, and that this difference between the observed attractions and repullions is owing to fome unperceived cause in the form of the experiment.

It must be observed also, that the attractions and Attractions repulfions, with the fame denfity and the fame diffances, and repul-were, to all fenfe, equal, except in the forementioned fins are c-anomalous experiments. The mathematical reader will qual at efee, that the above-mentioned irregularities are imper-stances. fections of experiment, and that the gradations of this function of the diffances are too great to be much affected by fuch small anomalies. The indication of the law is precise enough to make it worth while to adopt it, in the mean time, as a hypothesis, and then to select, with judgment, fome legitimate confequences which will admit of an exact comparison with experiment, on so large a scale, that the unavoidable errors of observation shall bear but an infignificant proportion to the whole quantity. We shall attempt this: and it is peculiarly fortunate, that this observed law of action between two fpheres gives the most easy access to the law of action hetween the particles which compose them; for Sir Isaac Newton has demonstrated (and it is one of his most precious theorems), that if the particles of matter act on each other with a force which varies in the inverse duplicate ratio of the distances, then fpheres, consisting of such particles, and of equal density at equal distances from the centre, also act on each other with forces varying in the fame proportion of the distances of their centres. He demonstrates the same thing of hollow spherical shells. He demonstrates that they act on each other with the same force as if all their matter were collected in their centres. And, laftly, he demonstrates that if the law of action between the particles be different from this, the feufible action of fpheres, or of hollow spherical shells, will also be different (fee Principia, I. Prop. 74,

&c. also Astronomy, Encycl. 307.).

Therefore we may conclude, that the law of electric Electric according to the state of attraction and repulfion is fimilar to that of gravitation, tion is inand that each of those forces diminishes in the same pro-versely as portion that the fquare of the distance between the parthe fquare ticles increase. We have obtained much which is former of the disticles increase. We have obtained much useful informa-flance. tion from this discovery. We have now full confirmation of the propositions concerning the mutual action of two bodies, cach overcharged at one end and undercharged at the other. Their evidence before given amounted only to a reasonable probability; but we now see, that the curve line, whole ordinates represent the forces, is really convex to the abscissa, and that Z+z' is always greater than Z' + z; from which circumstance all the rest follows of course.

Let us now enquire into the manner in which the Disposition redundant fluid, or redundant matter, is distributed in of fuch bodies; the proportion in which it fubfifts in bodies fluid when communicating with each other; the tendencies to redundant escape; the forces which produce a transference, &c. &c. or deficient.

In the course of this enquiry, a continual reference will be made to the following elementary proposition:

Let ABD (fig. 17.) be the base of a cone or pyra-Lemnia. mid, whose vertex is P, and axis PC; and let abd be another section of it by a plane parallel to the base; let these two circles, or fimilar polygons, consist of matter or fluid of equal and uniform denfity; and let P be a particle of fluid or matter; the attraction or repulsion of this particle for the whole matter or fluid in the figure ABD is equal to its attraction or repulsion for

the whole matter or fluid in a b d. For the attraction for a particle in ABD is to the attraction for a particle fimilarly placed in a b d as P c2 to PC2; and the number of particles in ABD is to that of those in abd as PC2 to Pc2; therefore the whole attraction for ABD is to that for abd as P c2 × PC2 to PC2 × P c2, or in the ratio of equality.

Cor. 1. The same will be true of the action of plates of equal thickness and equal density; or, in general, having fuch thickness and density as to contain quantities of matter or fluid proportional to their areas.

2. The action of all fuch fections made by parallel planes, or by planes equally inclined to their axis, are

in parallel

plates.

3. The tendency of a particle P to a plane, or plate of uniform thickness and density, and infinitely extended, or to a portion of it bounded by the same pyramid, is the fame, at whatever distance it be placed from the plate, and it is always perpendicular to it.

4. This tendency is proportional to the density and

thickness of the plate or plates jointly.

It is only in two or three fimple cases that we can propose to state with precision what will be the dispofition and action of the electric fluid in bodies; but we shall select those that are most instructive, and connected with the most remarkable and important phenomena.

Let A adD (fig. 18.) and EebH represent the Disposition fections of a part of two infinitely extended parallel plates (which we shall call A and E), consisting of solid conducting matter, in which the electric fluid can move without any obstruction, but from which it cannot escape.

First, Let them be both overcharged, A containing When both the quantity r. of redundant fluid, and E containing are over-

the quantity s, and let r be greater than s. charged,

The fluid will be difposed in the following manner: There will be two strata, A a b B and Gg b H, adjoining to the remote furfaces, in each of which the quantity $\frac{r+s}{2}$ will be crowded together as close as

2. Adjoining to the interior furface (that is, the furface nearest to E) of the plate A, there will be a stratum C c dD, containing the quantity - crowded to-

gether. 3. The adjacent fide of E will have a stratum E ef F, just sufficient for containing the quantity $\frac{r-s}{s}$ at its natural denfity. This stratum will be entirely exhausted

4. The spaces BbcC and FfgG will be in their

For a particle of fluid in the space BbcC is urged in the direction a d by the force $\frac{r+s}{2}$ (n° 91, 3.),

and in the direction da by the force $\frac{r-s}{2}$, therefore it is, on the whole, urged in the direction a d with the force s, which will balance the repulsion of the redundant fluid in the other plate. A particle of fluid in the space FfgG is repelled in the direction he by a force $\frac{r+s}{2}$ by the fluid in G g b H, and it is attracted in the same direction by the redundant matter in E ef F,

with the force $\frac{r-s}{2}$. These make a force r which balances the repulsion r of the other plate. No other difposition will be permanent; for if a particle be taken out from either ftratum A a b B or C c d D into the space between them, the repulsion from that stratum which it quitted is leffened, and the repulsion of the opposite stratum, joined to that of the other plate, will drive it back again. The same thing holds with respect

to the fluid in the other plate. Cor. 1. If the two plates be equally overcharged, all the redundant fluid will be crouded on the remote furfaces, and the adjacent furfaces will be in the natural

In the fecond place, let the plates be undercharged, When the and let r be the fluid wanting in A, and s the fluid are under wanting in E, and let s be greater than r; then,

1. The strata adjoining to A a and H b will be completely exhausted of sluid, and the redundant matter in each will be fuch as would be faturated by $\frac{r+s}{2}$.

2. The stratum CcdD will contain redundant sluid $\frac{s-r}{2}$, crowded close.

3. The stratum E ef F will be deprived of sluid, and the quantity abstracted is $\frac{s-r}{2}$.

4. The spaces B b c C and Ffg G are in the natural state.

The demonstration is the same as in the former case. Thirdly, Let A be overcharged, and E underchar When ged, A containing the redundant fluid r, and E want- are in of ing the fluid s; and let r be greater than s. Then, politella

1. The strata A a b B and Gg h H contain the re-

dundant fluid , crowded clofe.

2. The firstum C c d D contains the quantity $\frac{r+s}{2}$ crowded close.

3. The stratum E ef F is exhausted, and wants the quantity $\frac{r+s}{2}$.

4. The rest is in the natural state.

Cor. 2. If the redundant fluid in A be just sufficient to faturate the redundant matter in E, the two remote furfaces will be in their natural state, all the redundant fluid in A being crowded into the stratum CcdD, and all the redundant matter being in E ef F.

This disposition will be the fame, whatever is the distance or thickness of the plates, unless the redundant fluid in A be more than can be contained in the whole of E when crowded close.

When the two plates are overcharged, the fluid Preffuto prefies their remote furfaces with the force $\frac{r+s^2}{4}$, and $\frac{and \, ren}{dency \, n}$ would escape with that force if a passage were opened. It would enter the remote furfaces of two undercharged plates with the fame force; and, in either case, it would run from the inner surface of one to the ad-

jacent furface of the other, with the force $\frac{r-s}{s}$

If one be overcharged and the other undercharged, fluid would escape from the remote furface with the

force $\frac{r-s^2}{4}$, and would run through a canal between

them with the force $\frac{r+s^2}{4}$.

They repel or attract each other with the force $r+s^2$, according as they are both over or undercharged, or as one is overcharged and the other undercharged.

This example of parallel plates, infinitely extended, is the simplest that ean be supposed. But it cannot obtain under our observation; and in all cases which we can observe, the sluid cannot be uniformly spread in any stratum, but must be denser near the edges, or near the eentre, as they are overcharged or undercharged.

Difition Let ABD (fig. 19.) represent a sphere of perfectly modeling matter, overcharged with electric sluid, which is perfectly moveable in its pores, but cannot escape from the sphere. Let it be surrounded by conducting matter saturated with moveable sluid. It is required to determine the disposition of the sluid within and without this sphere.

Sir Isaac Newton has demonstrated (*Princ.* I. 70.) that a particle p, placed anywhere within this sphere, is not affected by any matter that is without the concentric spherical surface pqr in which itself is situated, therefore not affected by what is between the surfaces ABD and pqr. He also demonstrates, that the matter within the surface pqr acts on the particle p in the same manner as if the whole of it were collected in the centre C.

Hence it follows, that the redundant fluid will be all conflipated as close as possible within the external surface of the sphere, forming a shell of a certain minute thickness, between the spherical surfaces ABD and abd; and all that is within this (that is, nearer the centre C) will be in its natural state.

With respect to the distribution of the sluid in the furrounding matter, which we suppose to be infinitely extended, we must recollect that this shell of conflipated redundant fluid repels any external partiele of fluid in the same manner as if all were collected at C. Hence it is evident, that the fluid in the forrounding matter will be repelled, and, being moveable, it will recede from this centre; and there will be a space all round the fphere ABD which is undercharged, forming a shell between the concentric furfaces ABD and a \$ 8. This shell will contain such a quantity of redundant matter, that its attraction for a particle of fluid is equal to the repulsion of the shell of fluid crowded internally on the furface ABD. All beyond this furface a B & will be in its natural state; for this redundant matter acts on a particle of fluid, fituated farther from the centre, in the same manner as if all this redundant matter were collected in the eentre C. So does the redundant fluid in the constipated shell. Therefore their actions balance each other, and there is no force exerted on any particle of fluid beyond this deficient shell. This deficient shell will not affect the fluid in the sphere abd by Newton's demonstration. No other disposition will be permanent. But farther: This undercharged shell must be completely exhausted: for a particle of fluid placed between ABD and a B s will be more repelled by the fluid in the erowded shell within the surface ABD, than it is attracted by the redundant matter of its own shell that is less remote from the centre; and

it is not affected by what is more remote from the centre. Therefore the fluid without the sphere ABD cannot be in equilibrio, unless the shell between ABD and $\alpha\beta\delta$ be not only rarefied, but altogether exhausted of fluid.

If the sphere be undereharged, the space between ABD and abd will be entirely exhausted of sluid, and there will be a shell $\alpha\beta\delta$ of redundant matter surrounding the sphere. All within abd, and all without $\alpha\beta\delta$, will be in its natural state. It is unnecessary to repeat the steps of the same demonstration.

This valuable proposition is by the Hon. Mr Caven-

This would be the disposition in and about a glass Consequenglobe filled and furrounded with an ocean of water, ces of this and having redundant fluid within it, on the supposition disposition, that glass is impervious to the electric fluid. But it would not affect an electrometer, even supposing that the movements of the electrometer could be affected under water. Suppose the globe of water to be furrounded with air, and that the fluid is disposed in both in the manner here deferibed; it will be perfectly neu-.. tral in its action on any electrometer fituated in the air. But, by reason of the almost total immobility of the sluid in pure dry air, this state eannot foon obtain; and, till it obtain, the constipated shell within the glass must repel the fluid in an electrometer more than the partially rarefied shell of air, which furrounds the glass, attracts it. By the gradual retiring of the fluid in the furrounding air from the globe, the attraction of the deferted matter will come nearer to equality with the repulsion of the constipated shell within the glass, and the globe will. appear to have lost fluid. Yet it may retain all the redundant fluid which it had at the first. Therefore we are not to imagine that a body fimilar to this globe has no redundant electric fluid, or only a fmall quantity, because we observe it inactive, or nearly so.

Thus we fee, as we proceed, that the Æpinian theo-Verrified ry is adequate to the explanation of the phenomena. By the phenomena by the phenomena and amufing experiment, ufually called the ELECTRIC Well ex. WELL. See ELECTRICITY, Encycl. Sect. x. 4.

To fee it in perfection, make a glass vessel of globular shape, with a narrow mouth, fufficiently wide, however, to admit an electrometer suspended to the end of a glass rod of a crooked form, so that the electrometer can be presented to any part of the infide. Smear the outfide of the globe with fome transparent elammy fluid, such as syrup. Set it on an infulating stand (a wine glass), and electrify it positively. Hold the electrometer near it, anywhere without, and it will be strongly affected. Its deviations from the perpendicular (if the ball of the electrometer has also been electrified) will indicate a force inverfely as the square of the distance from the centre of the globe, pretty exactly, if the thread of the electrometer is of filk. Now letdown the electrometer into the infide of the globe. It will not be affected in any fensible degree, nor approach. or avoid any body that is lying within the globe. The electrometer may be held in all parts of the globe, and when brought out again, is perfectly inactive and neutral. But if the balls of the electrometer be touched with a wire, while hanging free within the globe, they will, on withdrawing the wire, repel each other; and when taken out, they will be found negatively electrified. The experiment succeeds as well with a metal globe; nay, even although the mouth be pretty wide; in which case, there is not a perfect balance of action in every direction. The electrometer may be made to touch the bottom of the globe, or anywhere not too near the mouth, without acquiring any fensible electricity; but if we touch the outlide with the electrometer, it will instantly be electrified and strongly repelled. Deep cylinders, and all round veffels with narrow mouths, exhibit the same faintness of electricity within, except near the brims, although strongly electric without; and even open metal cups have the interior electricity much diminished.

IOI Electric

Reflecting on this valuable proposition of Mr Cavenbodies are dish, we see clearly why an overcharged electric is only only super- superficially so; and that this will be the case even although we attempt to accumulate a great quantity of electricity in it, by melting it in a thin glass globe, and electrifying it while liquid, and keeping up the accumulating force till it becomes quite cold. The present writer, not having confidered the fubject with that judicious accuracy that Mr Cavendish exerted, had hopes of producing a powerful and permanent electric in this way, and was mortified and puzzled by the difappointment, till he faw his mistake on reading Mr Cavendish's differtation.

Cautions in

These observations also point out a thing which certain ex- should be attended to in our experiments for discoverperiments. ing the electricity excited in the spontaneous operations of nature, as in chemical composition and decomposition, congelation, fusion, evaporation, &c. It has been usual to put the substances into glass, or other nonconducting veffels, or into veffels which conduct very imperfectly. In this last case especially, the very faint electricity which is produced, instantly forms a compenfation to itself in the substance of the vessel, and the apparatus becomes almost neutral, although there may have been a great deal of electricity excited. It will be proper to consider, whether the nature of the experiment will admit of metalline veffels. In the experiments on metalline folutions, the best method seems to be, to make the vessel itself the substance that is to be diffolved.

Electricity matter.

103.

For fimilar reasons we may collect, without a more more near- minute examination, that bodies of all shapes, when ly propor- overcharged, will have the redundant fluid much denfer near the furface than in the interior parts; and denfer in all elevations, bumps, projections, angles, and near quantity of the ends of oblong bodies; and that, in general, the quantity of redundant fluid, or redundant matter, will be much more nearly proportional to the furfaces of bodies than to their quantities of matter. All this is fully proved by experience. The experiment of the electrified chain is a very beautiful one. Lay a long metal chain in an infulated metal dish furnished with an electrometer. Let one end be held an inch or two above the coil by a filk thread. Electrify the whole, and observe the divergency of the electrometer; then, gradually drawing up the chain from the coil, the electrometer will gradually fall lower, and lowering the chain again will gradually raife it.

We now see with how little reason Lord Mahon concluded that the point of his conductor, observed to be neutral, corresponded with his theory; namely, one of the media of a harmonic division. We see no reason

for beginning the computation at the extremity of the prime conductor. It certainly should not have been from the extremity. Had the prime conductor been a fingle globe, it should have begun from the centre of this globe. If it was of the usual form, with an outstanding wire, terminated by a large ball, the action of the body of the conductor should certainly have been taken into the account. In short, almost any point of the long-conductor might have been accommodated to

his Lordship's theory.

We might now proceed to investigate the distribution of the electric fluid in bodies exposed to the action of others, and particularly in the oblong conductors made use of in our preparatory propolitions. The problem is determinate, when the length and diameter of cylindric conductors are given; but even when the electric employed for inducing the electricity is in the form of a globe, we must employ functions of the distances that are pretty complex, and oblige us to have recourse to second fluxions. The mutual actions of two oblong conductors, of considerable diameters, give a problem that will occupy the first mathematicians; but which is quite improper for this scanty abstract. Nor is a minute knowledge of the disposition of the fluid of very important service. We may therefore content ourselves with a general representation of the state of the sluid in the following manner, which will give us a pretty distinct notion how it will act in most cases:

Let A (fig. 20.) be an overcharged sphere, and BC General r a conducting cylindric or prismatic body; draw be partion of the rallel to BC, and erect perpendiculars B b, C c, P p, disposition of the representation o &c. to represent the equable denfity of the fluid, when of the flui the conductor is in its natural state; but let Bd, Cr, Ps, &c. represent the unequal densities in its different points, while in the vicinity of the overcharged sphere. These ordinates must be bounded by a line dnr, which will cut the line bc in the point n of the perpendicular, drawn from the nentral point N of the conductor. The whole quantity of fluid in the conductor is represented by the parallelogram BC cb; which must therefore be equal to the space BC rnd: the redundant fluid in any portion CP or PN is represented by the spaces crtp, or tpn; and the redundant matter, or deficient fluid, in any portion BQ, is represented by bdvq. The action of this body on any body placed near it, depends entirely on the area contained between this curve line and its axis bc. The only circumstance that we can ascertain with respect to this curve is, that the variations of curvature in every point are proportional to the forces exerted by the sphere A; and are therefore inverfely as the squares of the distances from A. This property will be demonstrated by and bye. The place of n, and the magnitude of the ordinates, will vary as the diameter of the conductor varies. We shall confider this a little more particularly in some cases which will occur afterwards. We may consider the fimplest case that can occur; namely, when the conductor is, like a wire, of no fenfible diameter, nay, as containing only one row of particles.

Let AE (fig. 21.) be such a slender conducting ca- In a ver) nal; and let B b, C c, E e, &c represent the density sender a of the fluid which occupies it, being kept in this flate fluid mul of inequable denfity by the repultion for some over- be almost charged body. A particle in C is impelled in the di-equally rection CE by all the fluid on the fide of A, and in the tributel

direction

direction CA by all the fluid on the fide of E. The moving force, therefore, arises from the difference of these repulsions. When the diameter of the canal is constant, this arises only from the difference of density. The force of the element adjacent to E may therefore be expressed by the excess of Dd above Cc, and the action at the distance CD jointly. Therefore, drawing $\beta c \varepsilon$ parallel to AE, this force of the element E will be expressed by $\frac{d \delta}{c \delta^2} x$, repelling the particle in the direction CA. If CF be taken equal to CD, the force of the element at F will be expressed by $\frac{f v}{c \delta^2} x$, also impelling the particle in the direction CA. The joint action of these two elements therefore is $\frac{d \delta}{c \delta^2} \frac{f v}{x}$. If bc e were a straight line, we should have ds + f v always proportional to $c \delta$; and it might be expressed by $m \times c \delta$; m being a number expressing what part of $c \delta$ the sum of $d \delta$ and f v amounts to (perhaps $v \circ t$), or $v \circ t \circ t$. But in the case expressed in the figure, d s does not increase so fast as $v \circ t \circ t$, and $f \circ t \circ t$. However, in the immediate neighbourhood of any point C, we may express the accelerating force tending towards A by $\frac{m c \delta}{c \delta^2} x$, with-

out any fensible error; that is, by $m = \frac{x}{2}$; that is, by the fluxion of the area of a hyperbola HD'G, having CC and CK for its affymptotes; and the whole action of the fluid between F and D, on the particle C, will be expressed by the area C'CDD'H. Hence it follows, that the action of the smallest conceivable portion of the canal immediately adjoining to C on both fides, or the difference of the actions of the two adjoining elements, is equal to the action of all beyond it. This shews, that the state of compression is hardly affected by any thing that is at a fensible distance from C; and that the denfity of the fluid, in an indefinitely slender canal, is, to all fense, uniform. The geometer will also see, that the second fluxion of D d is proportional to the force of the distant body. We learn, therefore, so much of the nature of the curve bce. (Coulomb).

We are now in a condition to examine the communication of electricity by means of conducting canals (which is one of the most important articles of the fludy), having found that the fluid, in a very slender canal, is very nearly of uniform density throughout.

i- There can be no doubt but that, if a body B (fig. d 22.) be overcharged or undercharged, any other body C, which communicates with it by a conducting canal, will also be overcharged or undercharged. It is as evident, that if a body, in any state of electricity, be in the neighbourhood of an overcharged or undercharged body A, while it communicates with C by a canal leading from the side most remote from A, sluid will be driven from B into C, or abstracted from C into B.

leads from the fide nearest to A (as in fig. 23.), fluid will be driven from B into C. We conceive the fluid to be moveable in the body and in this canal, but not to escape from it. Its motion, therefore, in this case, should, in the opinion of Mr Cavendish, resemble the

running of water in a fyphon by the pressure of the air. While the repullion of the redundant fluid in A allows the bend of the fyphon nearest to A to retain fluid, a current should take place from B along the short leg, in consequence of the superior action on the sluid in the long leg. But if the repulsion of A can drive the fluid out of the bend between E and F, Mr Cavendilh thinks, that it does not appear that fluid will come up from B in opposition to the repulsion of A, and then run along to D. But fluid does not move, in either of these cases, on the principle of a syphon; because there is nothing to hinder the fluid from expanding in the part EDF. And we are rather disposed to think, that it will always move from B, over the bend, to C: For even if the fluid can be completely driven out of the bend EF, it must be done by degrees, and the suid in the long leg will, from the very beginning of the action of A, be more moved from its place than that in the short leg; and therefore will yield to the compression, which acts transversely, and, by thus yield. ing more toward F than toward E, the fluid will rush through the contrasted part, and go into C. We do not fay this with full confidence; but are thus particular, on account of an important use that may be made of the experiment. For if the body A be underchar-Propofal ged, fluid will certainly be attracted from C, and pass for discoversover the bend into B, however great the action of A dancy of may be. Perhaps this may be so contrived, therefore, fluid. as to decide the long agitated question, Whether the elec-tricity of excited glass be plus or minus? If it be found that this apparatus, being prefented to the rubber of an electrical machine, diminishes the positive electricity of C, and increases that of B; but that, presenting the fame apparatus to the prime conductor, makes little change-we may conclude, that the electricity of the prime conductor is positive. We have tried the expetiment, paying attention to every circumstance that feemed likely to infure fuccess; but we have always found hitherto, that the apparatus was equally affected

by both electricities.

We must now consider the action of electrified bodies on the canals of communication; because this will give us the easiest method of ascertaining the proportion in which the expelling studies distributed between them. For when two bodies communicate by a canal, and have attained a permanent state, we must conceive that their opposite actions on the studies moveable along this canal are in equilibrio, or are equal. This will generally be a much easier problem than their action on each other, since we have seen a little ago, that the studies in a stender canal is of uniform density very nearly. A very sew examples of the most important of the simple cases must suffice.

Therefore let AC a (§g. 24) represent the edge of Action of a a thin conducting circular plate, to which the stender plate on a canal CP is perpendicular in the centre. It is required rectilineal to determine the action of the matter or sluid, uniformly spread over this plate, on the sluid moveable in the canal PC?

1. Required the action of a particle in A on the fluid in the whole caual? Join AP; and call CPx, APy, and ACr; and let f express the intensity of action at the distance 1, or the unit of the scale on which the lines are measured.

The action of A on P, in the direction AP, is $\frac{f}{y^2}$.

AE

This.

1099

SUPPL. VOL. I. Part II.

PII.

This, when estimated in the direction CD, is reduced to $\frac{f}{y^2} \times \frac{x}{y}$; and is therefore $= f \frac{x}{y^3}$. Therefore the fluxion of the action, in the direction CP, on the whole canal, is $f \frac{x}{y^3} \dot{x} = f \frac{y \dot{y}}{y^3}$ (because $x : y = \dot{y} : \dot{x} = f \times \frac{\dot{y}}{y^2}$. The variable part of the fluent is $= f \times \frac{\dot{y}}{y}$, and the complete fluent is $= f \times \frac{1}{y}$, and the complete fluent is $= f \times \frac{1}{y}$.

 $f = \frac{1}{y}$, and the complete fluent is $= f(C - \frac{1}{y})$, where C is a constant quantity, accommodated to the nature of the case. Now, the action must vanish when the canal vanishes, or when x = 0, and y = r. There-

fore $C - \frac{1}{r} = 0$, and $C = \frac{1}{r}$; and the general ex-

preflion of the action is $f\left(\frac{1}{r} - \frac{1}{y}\right)$, $= f\frac{y-r}{ry}$, exprefling the action of a particle in the circumference of the plate on the fluid in the whole canal CP.

2. Required the action of the plate, whose diameter

is A a, on the particle P?

Let a represent the area of a circle, whose diameter gle particle is = 1. Then ar^2 is the area of the plate, and 2 arr with the canal is the fluxion of this area; because r: y = y: r, 2 a rr is = 2 ay y. Therefore the fluxion of the action of the plate on the particle P is $f \times 2 ay y \times \frac{x}{y^3}$, = $2 f a \times \frac{y}{y^2}$. The fluent of this has for its variable part $2 f a \times \frac{y}{y^3}$ (for when the particle P is given, x does

not vary). This is $= 2 f a \times \frac{-x}{y}$. To complete this fluent, we must add a constant quantity, which shall make the fluent = 0 when the particle P is at an infinite distance; and therefore when x = y. Therefore

 $\frac{y}{y} - \frac{x}{y} = 0$, or $1 - \frac{x}{y} = 0$, or C = 1; and the com-

plete fluent for the whole plate is $2 f a \left(1 - \frac{x}{y}\right)$.

The meaning of this expression may not occur to the reader: For $1 - \frac{x}{y}$ is evidently an abstract number; so is a. Therefore the expression appears to have no reference to the size of the plate. But this agrees with the observation in 10° 91. where it was shewn, that provided the angle of the cone or pyramid remained the same, the magnitude of the base made no change in its attraction or repulsion for a particle in the vertex.

It will appear by and bye, that $1 - \frac{\kappa}{y}$ is a meafure or function of a certain angle of a cone.

Cor. If PC be very small in proportion to AC, the action is nearly the same as if the plate were infinite: For when the plate is infinite, $\frac{x}{y}$ is = 0, and the action is = 1, whatever is the distance (see n° 91–93). Therefore, when x is very small in comparison of r, and consequently of y, $1 - \frac{x}{y}$ is very nearly = 1.

3. To find the action of the plate on the whole co- to the lumn?

The fluxion of this must be $= 2 f a \times (1 - \frac{x}{y}) \alpha$, canal.

or $2 f a \left(x - \frac{x \cdot x}{y} \right)$, or $2 f a \times (x - y)$; because $y = \frac{x \cdot x}{y}$

 $\frac{x \times x}{y}$. The fluent of this has for its variable part $2fa \times (x-y)$. A conftant quantity must be added, which shall make it = 0 when the column = 0; that is, when y=r, and x=c; that is, C-r=c, and C=r. Therefore the complete fluent is =2fa(x+r-y).

Thus have we arrived at a most simple expression of Geometric the attraction or repulsion of a plate for such a column, and it is most earlier or for portions of such a column. And it is most earlier of silvy constructed geometrically, so as to give us a femilie action, image of this action of easy conception and remembrance. It is as follows: Produce PC till CK = CA, and about the centre P describe the arch AI, cutting CK in I. Then $2 \int a \times IK$ is evidently the geometrical expression of the attraction or repulsion. This is plainly a cylinder, whose radius is a unit of the scale, and whose height is twice FK.

In like manner, by describing the arch Ai round the centre p, we have $2fa \times i K$ for the action of the plate on the small column Cp; and $2fa \times Ii$ is the

action of the plate on the portion Pp.

The general meaning of the expression $2fa \times IK$ is, that the action of the whole plate on the column PC is the same as if all the sluid in the cylinder $a \times 2IK$, were placed at the distance I from the acting particle.

From this propolition may be easily deduced fome very useful corollaries by the help of the geometrical configuration.

1. If PC be very great in comparison with AC, the action is nearly the same as if the column were infinitely extended; for in this case IK is very nearly = CK, the difference being to the whole nearly as AC to twice AP.

2. If, in addition to this last condition, another co-Import lumn p C be very small in comparison of AC, then the corolla action on PC is to that on p C very nearly as p C to AC. For it will appear that i K: IK = p C: AC very nearly. It is exactly so when CP: CA = CA: Cp; and it will always be in a greater proportion than that of p C to IK.

This will be found to be a very important observa-

The redundant fluid has hitherto been supposed to be uniformly spread over the plate: but this cannot be; because its mutual repulsion will cause it to be denser near the circumference. We have not determined, by a formula of easy application, what will be the variation of density. Therefore let us consider the result of the extreme case, and suppose the whole redundant fluid to be crowded into the circumference of the plate, as we saw that it must be on the surface of a globe.

In this case the action on the fluid in the canal will Adion be $fa(r-\frac{r^2}{y})$. For the area of the plate is ar^2 , and ence of the

the action of a particle in the circumference on the whole canal was shewn (n° 109.) to be $f\left(\frac{y-r}{ry}\right)$. Therefore the action of the whole fluid crowded into the circumference is $far^2 \times \frac{y-r}{ry}$, $= far\frac{y-r}{y}$. It may be represented as follows: Describe the quadrant C b BE, cutting AP and Ap in B and b. Draw BD and bd parallel to PC. Then PB = y-r, and DC = $r\frac{y-r}{y}$. Therefore the action is represented by f multiplying a cylinder, whose radius is 1 and height is DC. In like manner, dC is the height of the cylinder corresponding to the column p C, and D d the height corresponding to Pp.

Cor. 1. When CP is very great in comparison with CA, the point D is very near to A, and I is very near to C, and CD is to IK nearly in the ratio of equality. In this case the action of the fluid, uniformly spread over the plate, is nearly double of the action of the same fluid crowded round the circumference; for they are as cylinders, having the same bases and heights in the ratio of 2 IK to DC, which is nearly the ratio of

2 to 1.

2. On the other hand, when the column p C is very thort, the action of the fluid spread uniformly over the plate is to its action, when crowded round the circumference, nearly in the ratio of 4 AC to p C. For these actions are in the ratio of $2fa \times i$ K to $1fa \times d$ C, or as 2i K to d C, or nearly as 2p C to d C, or more nearly as 2bd to d C. But Cd:bd=bd:b A +Ad, or nearly =bd:2 CA. Therefore Cd:2bd

= pC : 4 CA nearly.

Hence we fee that the action on fhort columns is much more diminished by the recess of the redundant stud toward the circumference than that on long columns. Therefore, any external electric force which tends to fend shuid along this canal, and from thence to spread it over the plate, will fend into the plate a greater quantity of shuid than if the shuid remained ultimately in a state of uniform distribution over its surface; and that the odds will be greater when the canal is short.

AP, or PL be equal to KI, the repulsion which all the fluid in the plate, collected in K, would exert on the fluid in the canal CL, is equal to the repulsion which the fame fluid, constipated in the circumference, would exert on the column CP. For we have seen that the action of a particle in A on the whole column

PC, when estimated in the direction PC, is $\frac{y-r}{yr}$; and it is well known that the action of a particle in K for the column CL is $\frac{1}{KC} - \frac{1}{KL}$, or $\frac{1}{r} - \frac{1}{y}$, $= \frac{y-r}{yr}$. Therefore the action of the whole sluid, collected in the circumference, on the column CP is equal to that of the same sluid, collected in K, on the columns CL.

Cor. 1. If the column CP is very long in proportion to AC or KC, the actions of the fluids in these two different situations are very nearly the same. The action of the fluid collected in K exceeds its action when collected in A only by its action on the small and remote column LP. The action of all the fluid collect-

ed at K on the column CP, is easily had by taking C = KP. It is equal to the action of the same fluid placed in A on the column C l.

Cor. 2. The action of all the fluid uniformly spread, exerted on the column CP, is to the action of the same fluid collected in K, exerted on the column CL, as

2 IK to CD.

If the column CP is very great in proportion to AC, the half breadth of the plate, the action in the first case is very nearly double of the action in the other case, and is exactly in this proportion if CP is of infinite extent.

Cor. 3. If CNO be a spherical surface or shell of Action of a the same thickness and diameter as the plate A a, and spherical containing redundant shuid of the same uniform density, shell, or the action of this shuid on the column CL is double of solid, on the action of the shuid uniformly spread over the plate same on the column CP, and quadruple of the action of the canal. shuid collected in the circumference: for the action is the same as if all were collected in the centre K, and the surface of the sphere is four times that of the plate, and therefore they are as IK to 2 CD.

Let us now confider the comparative actions of different plates or fpheres on the canals.

If two circular plates, DE, de (fig. 25.), or two Actions of? fpherical shells, ABO, abo, of equal diameters and two plates, thickness with the plates and execution the plates. thickness with the plates, and containing redundant spheres, are fluid of equal denfity, communicate with infinitely ex-as their diatended straight canals OP, op, passing through their meters, centres perpendicular to their furfaces, also containing when the fluid uniformly diffributed and of equal dentity—the infinitely repulsions will be as the diameters. For the repulsionlong, of the spherical surfaces is the same as if all the sluid were collected at their centres; and the repulsion of the fluid uniformly spread over the surfaces of the plates is double of its repulsion if collected at the centres of these spheres; it follows, that the repulsions of the plates are proportional to those of the spheres. But because the repulsion of a plate whose radius is r was Thewn to be $= 2 a \times r + x - y$, and when the column is infinitely extended, x is equal to y, and r + x - y= r, it follows, that the repulsions of the plates are as $2 a \times R$ and $2 a \times r$, or proportional to their diameters, Therefore the repulsions of the spheres are in the same proportion.

Cor. 1. If the canals are very long in proportion tothe diameters of the plates or spheres, the repulsions are

nearly in the same proportion.

Cor. 2. But as the lengths of the canals diminish, the The prorepulsions approach to equality; for it was shewn, that portion of when the canal was very finall, the repulsion was to the greatest that for an infinite column as the length of the canalminished it to the radius of the plate. Therefore if the radius the canals of the greater plate be (for example) double of that are thort. of the smaller, and the little column be roth of the radius, it will be roth of the radius of the smaller plate. Now roth of half the repulsion is equal to roth of the double repulsion. Also, in the case of the spleres, the repulsion of a particle at the surface is as the quantity of fluid directly, and as the square of the radius inversely; but when the density is the same in both shells, the quantity is as the surface, or as the square of the radius. Therefore the repulsions are equal.

Cor. 3. If the denfity of the fluid in two fpherical fields be inverfely as the diameters, the repulsions for an

1220

299

104

123

Or if the

infinitely extended column of fluid are equal; for each Actions of repels as if all the fluid was collected in the centre. is actually so; and this confirms the opinion. are equal if Therefore, if the density, and consequently the quanthe density tity, be varied in any proportion, the repulsion will vary be inverfely in the same proportion. The repulsions will now be

as CO $\times \frac{1}{\text{CO}}$ to $co \times \frac{1}{co}$, or in the ratio of equality.

Cor. 4. When the quantities of redundant fluid in quantity of two spheres are proportional to their diameters, their redundant repulhons for an infinitely extended canal are equal: for if this redundant fluid is conflipated in the surfaces of the spheres, as it always will be when they consist of conducting matter, the denfities are as the diameters inversely, because the surfaces are as the squares of the diameters. Therefore, by the last corollary, their actions on an infinitely extended canal are equal. But in spheres of nonconducting matter it may be differently disposed, in concentric shells of uniform density. This makes no change in the action on the fluid that is without the sphere, because each shell acts on it as if it were all collected in the centre. Therefore the repulsions are still equal.

Cor. 5. Two overcharged spheres, or spherical shells, OAB, oab (fig. 26.), communicating by an infinitely extended canal of conducting matter, contain quantiged in this ties of redundant fluid proportional to their diameters; for their actions on the fluid in the interjacent canal must be in equilibrio, and therefore equal. This will communi- be the case only when the quantities of fluid are in the

cating by a proportion of their diameters.

When the canals are very long in proportion to the diameters of the spheres, the proportion of the quantities of redundant fluid will not greatly differ from that

of the diameters.

Cor. 6. When the fpheres of conducting matter are thus in equilibrio, the pressures of the sluid on their furfaces are inverfely as their diameters; for the repulfion of a particle at the furface is the same with the tendency of that particle from the centre of the sphere, the actions being mutual. Now this is proportional to the quantity of redundant fluid directly, and to the fquare of the distance from the centre inversely, that is, to the diameter directly, and to the square of the diameter inversely, that is, to the diameter inversely.

the diameter.

Hence it follows, that the tendency to escape from of the fluid the spheres is inversely as the diameter, all other cirto escape is cumstances being the same: for in as far as the escape invertily as proceeds from mere electric repulsion, it must follow this proportion. But there are evident proofs of the co-operation of other physical causes. We observe chemical compositions and decompositions accompanying the escape of electric fluid, and its influx into bodies: we are ignorant how far, and in what manner, these operations are affected by distance. Boscovich shews most convincingly, that the action of a particle (of whatever order of composition), on external atoms and particles, is furprifingly changed by a change in the distance and arrangement of its component atoms. A constipation, therefore, to a certain determined degree and lineal magnitude, may be necessary for giving occasion to some of those chemical operations that accompany, and perhaps occasion, the escape of the electric fluid. If this be the case (and it is demonstrable to be possible, if the operations of Nature be owing to attrac-

THE public is indebted to Mr Cavendish for the preceding theorems on the action of spheres and circular plates. He has given them in a more abstract and general form, applicable to any law of electric action which experience may warrant. We have accommodated them to the inverse duplicate ratio of the distances, as a point fufficiently established; and we hope that we have rendered them more simple and perspicu-We have availed ourselves of Mr Coulomb's demonstration of the uniform density in the canal, without which the theorems could not have been demonstrated. The minute quantity of the fluid in the canal can have no fensible effect on the disposition or pro-

portion of the fluid in the plates or fpheres.

It may be thought that the last corollary, respecting Thisprop the equilibrium of two spheres, is not agreeable to hy-fit onage. drostatical principles, which require the equality of the drostate two forces which balance each other at the orifices of laws, the flender cylindric canal; whereas, in that corollary, the forces at the extremities of the canal are inverfely as the diameters of the fpheres or plates. This would be a valid objection, if the compressing forces acted only on the extremities of the canals; but they act on every particle through their whole length. It is not, therefore, the pressure at one end of the canal that is in equilibrio with the preffure at the other end, by the interpolition of the fluid. It is the pressure at one end, together with the sum of all the intermediate preffures in that direction, that is in equilibrio with all the pressure in the opposite direction. The pressures at the ends are only parts of the whole opposite pressures; they are the fuft in each account. In this manner a flender pipe, having a ball at each end, may be kept filled with mercury, while lying horizontal, if the air in each ball is of equal density. But if it be raifed perpendicular to the horizon, it cannot remain filled from end to end, unless the air of the ball below be made so elastic by condensation, that its pressure on the lower orifice of the pipe exceed the pressure of the air in the upper ball on the other orifice by a force equal to the weight of the mercury, that is, to the aggregate of the action of gravity on each particle of mercury in the pipe. Therefore the repullions of the spheres that we are speaking of are in equilibrio by the intervention of the fluid in the canal, in perfect confiftency with the laws of hydrostatical pressure.

Mr Cavendish has pursued this subject much farther, and has confidered the mutual action of more than two bodies, communicating with each other by canals of moveable fluid uniformly denfe. But as we have not room for the whole of his valuable propofitions, we felected those which were elementary and leading theorems, or fuch as will enable us to explain the most important phenomena. They are also such, as that the attentive reader will find no difficulty in the investigation of

those which we have omitted.

Mr Cavendish's most general proposition is as follows: General When an overcharged body communicates, by a ca-proposition nal of very great length, firaight or crooked, with two feed to or more similar bodies, also at a very great distance state of from each other, and all are in electric equilibrium, and commun confequently cating be

130 Two Spheres overcharproportion librio if

131.

confequently each body overcharged in a certain determined proportion, depending on its magnitude, if any two of these bodies are made to communicate in the same manner, their degrees of electricity are such, that no fluid will pass from one to the other, their mutual actions on the sluid in this canal being also in equilibrio. He brings out this by induction and combination of the fingle cases, each of which he demonstrates by means of

the following theorem:

The action of an overcharged sphere ACB (fig. 25.) indifficult when on the fluid in the whole of a canal df P that is obtated. lique, stending to impel the fluids in the direction of that canal, is equal to its action on the fluid in the whole of the rectilineal canal CP. Let bi be a minute portion of the straight canal, and fd the portion of the crooked canal which is equidistant from the centre C of the sphere; draw the radii Cf, Cd, and the concentric arches bf, id, cutting fC in g; and draw g e perpendicular to fd; the force acting on ib, impelling it toward P, may be represented by bi. The fame force acting on df, in the direction ef, must therefore be expressed by gf. This, when estimated in the direction of the canal df, is reduced to ef; but it is exerted on each particle of df. Now df: gf = gf: ef, and $df \times ef = gf^2$, $= gf \times bi$; therefore the whole force on df, in the direction df, is equal to the force on ib, in the direction ib. Hence the truth of the proposition is manifest.

We beg the curious reader to apply this to the case in hand, and he will find, that the most complicated cases may all be reduced to the simple ones which we have demonstrated to be strictly true when the bodies are spheres or plates, and the canals infinitely long, and which are very nearly true when the canals are very long, and the bodies similar: And we now proceed to one compound case more, which includes all the most

remarkable phenomena of electricity.

Let HK, AB, DF, and LM (fig. 27.), be four parallel and equal circular plates, two of which, HK and AB, communicate by a canal GC of indefinite explanes; let DF and LM be connected in the fame manner, and let the two canals be in one straight line; let the plate HK be overcharged, and the plate LM just faturated. It is required to determine the disposition and proportion of the electric stuid in the plates which will make this condition of HK and LM possible and permanent, every thing being in equilibrio?

The plate HK being overcharged, and communicating with AB, AB must be overcharged in the same manner, and being also equal to HK, it must be overcharged in the same degree, containing an equal quantity of redundant sluid disposed in the same manner. To simplify the investigation, we shall first suppose that the redundant sluid is uniformly spread over the surfaces

of both.

When the plates HK and AB are in this state, let the plates DF and LM be brought near them, as is represented in the figure, CE being the distance of the centres of AB and DF. It is evident, that the redundant shuid in AB will act on the natural moveable shuid in DF, and drive some of it along the canal EN, and render LM overcharged. Take off this redundant shuid in LM. This will diminish or annihilate the repulsion which it was beginning to exert on the canal

EN; therefore more fluid will come out of DF, and again render LM overcharged. The redundant fluid in LM may again be taken off, in less quantity than before, as is plain. Do this repeatedly till no more can be taken off. But this will undoubtedly render DF undercharged, and it will now contain redundant matter. This will act on the fluid in the canal GC, and abstract it from G; therefore fluid will come out of HK into AB. HK will be lefs overcharged than before, and AB will be more overcharged. But the now increased quantity of redundant fluid in AB will act more strongly on the moveable fluid in DF, and drive more out of it. This will leave more redundant matter in it than before, and this will act as before on the fluid in the canal GC. 'This will go on, by repeatedly touching I.M, till at last all is in equilibrio Or this ultimate flate may be produced at once by allowing LM to communicate with the ground. And now, in this permanent state of things, HK contains a certain quantity of redundant fluid; AB coutains a greater quantity; DF contains redundant matter; and LM contains its natural quantity. The demand of the problem therefore is to determine the proportion of the redundant fluid in HK to that in AB, and the proportion of the redundant fluid in AB to the deficiency of fluid in DF. The dynamical confiderations which determine these proportions are, if, The repulsion of the redundant fluid in AB, for the fluid in the carril EN, must be precisely equal to the attraction of the redundant matter in DF for the fame fluid in the capal; for LM, being faturated, is neutral. 2d, The repulfion of the redundant fluid in HK, for the whole fluid in the canal GC, must balance the excess of the repulfion of the redundant fluid in AB above the attraction of the redundant matter in DF for the fame.

Let the redundant fluid in AB be = f. the redundant matter in DF = m. the redundant fluid in HK = F.

Because HK and AB are equal, there can be no doubt but that the fluid in those plates would be fimilarly disposed; and it is highly probable, that if AB be very near DF, the redundant fluid in AB, and the redundant matter in DF, will also be disposed nearly in the fame manner. This will appear plainly when we confider with attention the forces acting between a very fmall portion of AB and the corresponding portion of DF. The probability that this is the case is so evident, that we apprehend it unnecessary to detail the proofs. We shall afterwards consider some circumstances which shew that the disposition in the three plates will (though nearly fimilar) be nearer to a flate of uniform distribution than if only AB and HK had been in action. Assuming therefore this similarity of distribution, it follows, that their actions on the fluid in the canals will be fimilar, and nearly proportional to their quantities.

Therefore let 1 be to n as the repulsion of the sluid in AB, for the sluid that would occupy CE, is to its repulsion for the sluid in EN or CG.

Then the action of AB on EN is $f \times n - 1$, and the action of DF on EN is mn; therefore, because the plate LM is inactive, the actions of AB and DF on EN must balance each other, and $f \times n - 1 = mn$,

and
$$m = f \times \frac{n-1}{n}$$
.

The

135 Prodigious

accumula-

tion of re-

The repulsion of f for the fluid in CG is fn. The attraction of m for it is $m \times n - 1$; and because m $=f \times \frac{n-1}{n}$, the attraction of m for the fluid in CG is $f \times \frac{n-1}{n} \times \overline{n-1}$. Therefore the repulsion of fis to the attraction of m as f n to $f \times \frac{n-1}{n}$, or as $f n^2$ to $f \times \overline{n-1}^2$, or as n^2 to $\overline{n-1}^2$. Call the repulsion of f r, and the attraction of m a. We have $r: a = n^2 : n - 1^2$ and $r: r - a = n^2 : n^2 - (n - 1)^2 = n^2 : 2n - 1$.

Therefore, because the repulsion of F is equal to this excess of r above a, we have $n^2 : 2n - 1 = f$: F, and F $= f \frac{2n-1}{n^2}$, or $f = F \frac{n^2}{2n-1}$. Therefore, if n^2 is

much greater than 2n-1, the quantity of redundant fluid in AB will be much greater than the quantity in

Now, when the electric action is inverfely as the

fquare of the distance, and EC is very small in comparison with AC, we have seen (no 115.) that 1:n nearly = CE : CA, or that n is nearly $\frac{AC}{EC}$. When this is the case, and consequently n is a considerable number, we may take the number $\frac{n^2}{2n}$ for $\frac{n^2}{2n-1}$ without any

great error. In this case f is equal to $F \times \frac{n}{2}$ very nearly. Suppose CA to be fix inches, and CE to be $\frac{1}{2.0}$ th of an inch; this will give n = 120, and f = 60 F; or, more exactly, $F = \frac{n^2}{2n-1} = \frac{14,400}{239}$; = $60\frac{1}{4}$ If, instead of the plate HK, we employ a globe of the fame diameter, f will be but half of this quantity, or f

 $= F \times \frac{n}{4}$ (n° 123, 124.).

It also appears, that when the plates AB and DF And evacuare very near to each other, and consequently n a large ation : number, the deficiency in DF is very nearly equal to the redundancy in AB. In the example now given,

m is $\frac{59}{60}$ of f, being $= f \times \overline{n-1}$.

Vet no very Yet this great deficiency in DF does not make it Enfible ap- electrical on the fide toward LM. It is just fo much pearance. evacuated, that a particle of fluid at its surface has no tendency to enter or to quit it.

Lastly, this great quantity of sluid collected in AB does not render it more electrical than HK.

In general, things are in the condition treated of in

nº 22, 23, &cc.

The attentive reader will readily fee, that this account of the apparatus of four plates is only an approximation to the condition that really obtains under our obfervation. Our canals are not of indefinite length, nor occupied by fluid that is distributed with perfect uniformity; nor is the fluid uniformly spread over the furface of the plates. He will also see, that the real state of things, as they occur in our experiments, tends to diminish the great disproportion which this imaginary flatement determines. But when the canals are very long in comparison with the diameters of the plates,

and AB is very near to DF, the difference from this determination is inconfiderable. We shall note these differences when we confider the remarkable phenomena that are explained by them.

In the mean time, we shall just mention some simple confequences of the prefent combination of plates.

Suppose AB touched by a body. Electric fluid will Method be communicated; but by no means all the redundant of dettroyfluid contained in AB: only as much will quit it as great accuwill reduce it to a neutral state, if the body which mulation; touches it communicates with the ground; that is, till 1. By dethe attraction of the redundant matter in DF attracts grees; fluid on the remote fide of AB as much as the redundant fluid left in AB repels it. When this has been done, DF is no longer neutral; for the repulsion of AB for the sluid in EN is now diminished, and therefore the attraction of DF will prevail. If we now touch DF, it may again become neutral with respect to EN; but AB will now repel again the fluid in CG, and again be electric on that fide by redundancy. Touching AB a fecond time takes more fluid from it, and DF again becomes electric by deficiency, and attracts fluid on that fide. - And thus, by repeatedly touching AB and DF alternately, the great accumulation of fluid in AB may be exhausted, and the nearly equal deficiency in DF may be made up.

But this may be done in a much more expeditious 2. All at way. Suppose a flender conducting canal abd brought once. very near to the outfides of the plates, the end a being near to A, and the end d to D. The vicinity of a to A causes the fluid in ab to recede a little from a by the repulsion of the redundant fluid in AB. This will leave redundant matter in a, which will ftrongly attract the redundant fluid from A, and a may receive a spark. But the consequence, even of a nearer approach of the fluid to the outward furface of A, will render the corresponding part of DF more attractive, and the retiring of fluid from a along ab will push some of its natural fluid toward d; and thus A becomes more disposed to give out, and a to take it in, while d is disposed to emit, and D to attract. Thus every circumstance favours the passage of the whole, or almost the whole, redundant fluid to quit AB at A, to go

It is plain, that there must be a strong tendency in The places the fluid in AB to go into DF, and that the plates tract each must strongly attract each other. A particle of sluid other. fituated between them tends toward DF with a force, which is to the fole repulsion of AB nearly as twice the redundant fluid in it to what it would contain if

WITH this particular and remarkable case of induced electricity, we shall conclude our explanation of Mr Æpinus's Theory of Electric Attraction and Repullion. The reader will recollect, that we began the confideration of the disposition of the electric fluid in bodies, in order to deduce such legitimate consequences of the hypothetical law of action as we could compare with the phenomena.

These comparisons are abundantly supplied by the Method of preceding paragraphs, particularly by no 74, 75, 76; examining the validit by no 130, and by no 134.

Let a fmooth metal sphere be electrified positively of this the any manner whatever, and then touch it with a small in any manner whatever, and then touch it with a small

along abd, and to enter into DF at D.

electrified to the same degree while standing alone.

one in its natural state. The redundant stuid is divided between them in a proportion which the theory determines with accuracy. By the theory also the redundant stuid in both acts as if collected in the centre. Therefore the proportion of the repulsions is determined. These can be examined by our electrometer. But, as this mensuration may be said to depend on the truth of the theory, we may examine this independent of it. Let the balls be equal. Then the redundant stuid is divided equally between the bodies, whatever be the law of action. Therefore observe the electrometer, as it is affected by the electrified body, both before and after the communication. This will give the positions of the electrometer which correspond to the quantities 2 and 1.

Take off the electricity of one of the balls by touchuation tro- ing it, and then touch the other ball with it. This will reduce to 1 the original quantity 1, and therefore to 1/4th of the original quantity. This will determine the value of another polition of the electrometer. In like manner, we obtain ith, toth, &c. &c. Then, by touching a ball containing I with a ball containing 1/2, we get a position for $\frac{1}{4}$, $\frac{3}{4}$, $\frac{3}{8}$, &c. Proceeding in this way, we graduate our electrometer independently of all theory, and can now examine the electricity of bodies with confidence. The writer of this article took this method of examining his electrometer, not having then feen Mr Cavendish's differtation, which gives another mode of measurement. He had the satisfaction of obferving, in the first place, that the positions of the inftrument which unquestionably indicated 1, 1, 4, &c. were precifely those which should indicate them if electric repulsion be inversely as the squares of the distances. Having thus examined the electrometer, it was cafy to give to balls any proposed degree of electricity, and then make a communication between balls of very different diameters. The electrometer informed us when the repeated abstractions by a finall ball reduced the electricity of a large ball to 1, 1, &c. This shewed the proportion of electricity contained in balls of dif-ferent diameters. This was also found to be such as refulted from an action in the inverse duplicate ratio of the distances.

Long after this, Mr Cavendish's investigation pointed out the proportion of the redundant electric sluid in balls of different sizes joined by long wires; in 130, &c. these were examined—and found to be such as were

fo indicated by the electrometer.

And, lastly, the mode of accumulating great quantities of sluid by means of parallel plates, gave a third way of confronting the hypothetical law with experiment. The argument was no less satisfactory in this ease; but the examination required attention to particulars not yet mentioned, which made the proportions between the sluid in HK and AB (fig. 27.) widely different from those mentioned in the preceding paragraphs. These circumstances are among the most curious and important in the whole study, and will be considered in their place.

We rest therefore with considence on the truth of west the law of electric action, assumed by us as a principle act of explanation and investigation. It is quite needless and unprositable to give any detail of the numerous experiments in which we confronted it with the phenomena. The scrupulous reader will get ample satis-

faction from the excellent experiments of Mr Coulomb with his delicate electrometer. He will find them in the Memoirs of the Academy of Sciences of Paris for 1784, 1785, 1786, and 1787. Some of them are of the fame kind with those employed by the writer of this article; others are of a different kind; and many are directed to another object, extremely curious and important in this fludy, namely, to discover how the electric fluid is disposed in bodies; and a third set are directed to an examination of the manner in which the electric fluid is dissipated along imperfect conductors.

But we have already drawn this article to a great length, and must bring it to an end, by explaining some very remarkable phenomena, namely, the operation of the Leyden phial, the operation of the clectrophorus, and the dissipation of electricity by sharp points and by imperfect conductors.

The observations of Mr Watson on the necessity of Of the Leyconnecting the rubber of an electrical machine with the den phial. ground, might have fuggested to philosophers the doctrine of plus and minus electricity, especially after the valuable discoveries of Mr Symmer and Cigna. A serious confideration of these general facts would have led to the theory of coated glass almost at its first appearance. But the historical fact was otherwise; and a considerable time elapsed between the first experiments with charged glass by Kleift, and the clear and fatisfactory account given by Dr Franklin, of all the effential parts of the apparatus, and the probable procedure of nature in the phenomenon. The impermeability of glass by the electric fluid, and the consequent abstraction of it from the one fide while it was accumulated on the other, fuggested to his acute mind the leading principle of electrical philosophy; namely, that all the phenomena arise from the redundancy or deficiency of electric fluid, and that a certain quantity of it resides naturally in all bodies in a flate of uniform distribution, and, in this state, produces no sensible effect. This was, in his hands, the inlet to the whole science; and the greatest part of what has been since added is a more distinct explanation how the redundancy or deficiency of electric fluid produces the observed pheno-Dr Franklin deduced this leading principle from observing, that as fast as one side of a glass plate was electrified positively, the other side appeared negative, and that, unless the electricity of that fide was communicated to other bodies, the other fide could be no farther electrified. Having formed this opinion, the old observations of Watson, Symmer, and Cigna, were explained at once, and the explanation of the Leyden phial would have come in course. It is for these reafons, as much as for the important discovery of the fameness of electricity and of thunder, that Dr Franklin stands so high in the rank of philosophers, and is justly considered as the author of this department of natural science. Whatever credit may be due to the chemical speculations of De Luc, Wilcke, Winkler, and many others, who have attempted to affociate electricity with other operations of nature, by refolving the electric fluid into its constituent parts, all their explanations prefuppose a mathematical and mechanical doctrine concerning the mode of action of the ingredients, which will either account for the total inactivity of the compound, or which will explain, in the very fame manner, the action of the compound itself : yet all feem

d en

to content themselves with a vague and indistinct notion of this preliminary step, and have allowed themfelves to speak of electrical atmospheres, and spheres of activity, and fuch other creatures of the mind, without once taking the trouble of confidering whether those assumptions afforded any real explanation. How different was Newton's conduct. When he discovered that the planets attracted each other in the inverse duplicate ratio of the distances, and that terrestrial gravity was an instance of the fame force, and that therefore the deflection of the earth was the effect of the accumulated weight of all its parts; he did not rashly affirm this of the planets, till he examined what would be the effect of the accumulated attraction in the abovemen-

tioned proportion.

Mr Æpinus has the honour of first treading in the steps of our illustrious countryman; and he has done it with fingular fuccess in the explanation of the phenomena of attraction and repulsion, as we have already feen. In no part of the study has his success been fo confpicuous as in the explanation of the curious and important phenomena of the Leyden phial. It only remained for him to account for the accumulation of fuch a prodigious quantity of this agent as was competent to the production of effects which seemed to exceed the fimilar effects in other cases, out of all proportion. Indeed, the disproportion is so great, as to make them appear to be of a different and incomparable nature. Dr Wilfon's experiments in the pantheon are therefore precious, by shewing that nothing was wanted for the production of all the effects of the Leyden phial but a furface sufficiently extensive for containing a valt quantity of fluid, and so perfectly conducting as to admit of its fimultaneous and rapid transference. 'l'herefore we affert, that one of the chief merits of Mr Æpinus's theory is the fatisfactory explanation of the accumulation of this vast quantity of fluid in a small space. We trust, therefore, that our readers will peruse it with pleasure. But we must here observe, that Mr Æpinus has not expressly done this in the work which we have already made fo much ufe of, nor in any other that we know of. He has gone no farther than to point out to the mathematicians, that his hypothesis is adequate to the accounting for any degree of accumulation whatever. This he does in that part of his work which contains the formulæ of no 38, 39, 40, 41, &c. And he afterwards shews, that all the phenomena of attraction and repulsion which are observed in the charged jar are precifely fuch as are necessary confequences of

148 Theory of charged difh,

It is to the Hon. Mr Cavendish that we are indebted for the fatisfactory, the complete (and we may call it the popular), explanation of all the phenomena. Mr Caven-Forming to himself the same notion of the mechanical properties of the electric fluid with Mr Æpinus, he examined, with the patience, and much of the address, of a Newton, the action of fuch a fluid on the fluid around it, and the sensible effects on the bodies in which it resided; the disposition of it in a considerable variety of cases; and particularly its action on the fluid conarrived at a fituation of things fimilar to the Leyden

We have given an abstract of this investigation accommodated to the inverse duplicate ratio of the distances.

From this it appears (n° 135), that whatever quantity of electric fluid we can put into a circular plate 12 inches in diameter, by fimple communication with the prime conductor of an electrical machine, we can accumulate 60 times as much in it by bringing the plate within the of an inch of another equal plate which communicates with the ground; and it appears in no 130, that all this accumulated fluid may be transferred in an instant to the other plate (which is shewn to be almost equally deprived of fluid), by connecting the two plates by a small wire.

But as it was also shewn in that paragraph, that the force with which the accumulated fluid was attracted by the redundant matter in the other place was exceedingly great, and confequently its tendency to escape was proportionably increased; this accumulation cannot be obtained unless we can prevent this spontaneous

transference.

Here the non-conducting power of idio electrics, Inexplicawithout any diminution, the action of the electric fluid ble by ma on fluid or matter on the other fide of them, comes to spheres. our aid, and we at once think of interpoling a plate of glafs, or wax, or rofin, or any other electric, between our conducting plates. Such is the immediate fuggestion of a person's mind who entertains the Æpinian notion of the electric fluid; and such, we are convinced, is the thought of all who imagine that they understand the phenomena of the Leyden phial. But those who attempt to explain electric action by means of what they call electric atmospheres of variable density or intensity, are not intitled to make any such inference, nor to expect any fuch phenomena as the Leyden phial exhibits. Electricity, they fay, acts by the intervention of atmospheres: Therefore, whatever allows the propagation of this action (conceive it in any manner whatever), allows the propagation of these agents; and whatever does not conduct electric action, does not conduct the agents. Interpoled glass should therefore prevent all action on the other plate. This is true, even although it were possible (which we think it is not) to form a clear notion of the free passage of this material atmosphere in an instant, and this without any diminution of its quantity, and confequently of its action, by the displacement of so much of it by the solid matter of the body which it penetrates. Yet without this undiminished action of the electrified plate on the fluid, and on the matter, beyond the glass, and on the canal by which its fluid may be driven off into the general mass-no fuch accumulation can take place; and if the phenomena of the Leyden phial are agreeable to the results of the Æpinian hypothesis, all explanation by atmospheres mult be abandoned. Indeed when the partisans of the atmospheres attempt to explain their conceptions of them, they do not appear to differ from what are called spheres of activity (a phrase first used by Dr Gilbert of Colchester, in his celebrated work De Magnete et Corporibus Magneticis): and spheres of activity will be found nothing more than a figurative tained in flender canals and in parallel plates; -till he expression of some indistinct conception of astion in every direction. When we use the words attraction and phial. And he then pointed out the precise degree of repulsion, we do not speak a whit more figuratively than accumulation that was attainable, on different supposi- when we use the general word action. These terms are tions concerning the law of electric action in general. all figurative, only attraction and repulfion have the ad-

vantage of specifying the direction in which we conceive fore DF, communicating with the ground, is brought the action to be exerted.

It therefore becomes still more interesting to the philosopher to compare the phenomena of CHARGED GLASS with the Æpinian theory. They afford an experimentum crucis in the question about electric atmospheres.

Let G (fig. 28.) represent the end of a prime con-Ph. mena rged ductor, furnished with Henley's electrometer. Let AB represent a round plate of tinfoil, pasted on a pane of glass which exceeds the tinfoil about two inches all round. The pane is fixed in a wooden foot, that it may stand upright and be shifted to any distance from the conductor. DF represents another plate of the fame dimensions as AB, in the centre of which is a wire EN, having a fmall ball on the end N, to which is attached a Canton's electrometer. This wire passes through the wooden ball O, fastened to the infulating stand P. The glass pane must be very clean, dry, and warm. Connect the conductor G with AB by a wire reaching to the centre C. Turn the cylinder of the electrical machine flowly, till the electrometer rife to 30° or 40°, and note the number of turns. Take off the electricity, and having taken away the connecting wire GC, turn the machine again till the electrometer rife to the fame height. The difference in the number of turns will give some notion of the expenditure of fluid necessary for electrifying the plate of tinfoil alone. This will be found to be very trifling when the electricity is in so moderate a degree. It is proper, however, to keep to this moderate degree of electrification, because when it is much higher, the dislipation from the edges of the plate is very great. Replace the wire, and again raife the electrometer to 30°. Now bring forward the plate DF, keeping it duly opposite and parallel to AB, and taking care not to touch it. It will produce no fenfible change on the position of the electrometer till it come within four or three inches of the glass pane; and even when we bring it much nearer (if a spark do not fly from the glass pane to DF), the electrometer HG will fink but two or three degrees, and the electrometer at N will be little affected. Now remove the plate DF again to the distance of two or three feet, and attach to its ball N a bit of chain, or filver or gold thread, which will trail on the table. Again, raife the electrometer to 30°, and bring DF gradually forward to AB. The electrometer HG will gradually fall down, but will rife to its former height, if DF be withdrawn to its first fituation. It is scarcely necessary to shew the conformity of this to the theory contained in no 134, 135, &c. As the plate DF approaches, the redundant fluid in AB acts on the fluid in DF, and drives it to the remote end of the wire EN, as was shewn by the divergency of the balls at N; and then an accumulation begins in AB, and the electrometer HG falls, in the same manner as if part of the fluid in the prime conductor were communicated to AB. When DF communicates with the ground, the electrometer at N cannot shew any electricity, but much more fluid is now driven out of DF, in proportion as it is brought nearer to AB. Instead of connecting AB immediately with the prime conductor, let the wire GC have a plate at the end G, of the fame dimensions as AB, having an electrometer attached to the fide next to AB. Let this apparatus of two plates be electrified any how, SUPPL. VOL. I. Part II.

near it, and then attend to the changes. We shall find the divergency of this electrometer correspond with the distance of DF very nearly as the theory requires.

While the plates AB and DF are near each other, State of the especially when DF communicates with the ground, if coatings. we hang a pith-pall between them by a filk thread, it will be strongly attracted by the plate which is nearest to ic, whether DF or AB; and having touched it, it will be briskly repelled, and attracted by the glass pane, which will repel it after contact, to be again attracted and repelled by DF; and thus bandied between the plates till all electricity disappear in both, the electrometer attached to H descending gradually all the

As all these phenomena are more remarkable in proportion as the plates are brought nearer, they are most of all when DF is applied close to the glass pane. And if, in this fituation, we take any accurate method for measuring the intensity of the electricity in the plate HG, before the approach of DF, we shall find the diminution, occasioned by its coming into full contact with the pane, confiderably greater than what is pointed out in no 135. When we employed plates of 12 inches diameter, pasted on a pane one-fortieth of an inch in thickness, we found the diminution not less than 199 parts of 200; and we found that it required at least 200 times the revolution of the cylinder to raise the electrometer to the fame height as before. This comparison is not susceptible of great accuracy, by reafon of many circumstances, which will occur to an electrician. But in all the trials we have made, we are certain that the accumulation greatly exceeded that pointed out by the Æpinian theory as improved by Mr Cavendish. And we must here observe, that we found this superiority more remarkable in some kinds of glass than others, and more remarkable in fome other idioelectrics. We think that in general it was most remarkable in the coarse kinds of glass, provided they were uniformly transparent. We found it most remarkable in fome common glass which had exfoliated greatly by the weather: but we also found that such glaffes were very apt to be burst by the charge. The hardest and best London crown-glass seemed to accumulate less than any other; and a coloured glass, which when viewed by reflection feemed quite opake, but appeared brown by transmitted light, admitted an accumulation greatly exceeding all that we have tried; but it could not be charged much higher without the certainty of being burst. This diversity in the accumulation, which may be made in different kinds of glass, hinders us from comparing the abfolute accumulations affigned by the theory with those which experiment gives us. But though we cannot make this comparison, we can make others which are equally fatisfactory. We can discover what proportion there is between the accumulation in glass of the same kind, as it may differ in thickness and in extent of furface. Using mirror glass, which is of uniform and measurable thickness, and very flat plates, which come into accurate or equable contact we found that the accumulation is inverfely as the thickness of the plates; but with this exception, that when two plates were used instead of a plate of double thickness, the diminution by the increase of thickness and note the divergency of the electrometer at H, be- was not nearly in the proportion of this increase. In-

153×

stead o' being reduced to one-half, it was more than two thirds; and in the kind called Dutch plate, the diminution was inconsiderable.

Strong attraction between them.

The experiments with the Dutch and other double plates, fuggested another instructive and pretty experiment. Observing these plates to cohere with considerable force, it was thought worth while to measure it; which was attempted in this manner: Two very flat brass plates AB, DF (fig. 29.), furnished with wires and balls, were suspended, about three inches asunder, by filk threads, as represented in the figure. At G was attached a very fine filver wire, which hung very loose between it and the prime conductor, without coming near the table. Another was attached to N, which touched the table. A plate of mirror glass was fet between them, as shewn by QR. When this apparatus was electrified, the threads of fuspension immediately began to deviate from the perpendicular, and the plates to approach the glass pane and each other. The pane was carefully shifted, so as to be kept in the exact middle between them. This result shewed very plainly the pressure of the sluid on one of the plates, and the mutual attraction of the redundant matter and redundant fluid. This increased as the accumulation increased; and it was attempted to compare the attraction with the accumulation, by comparing the deviation of the fufpending threads with that of the electrometer attached to the prime conductor; but we could not reconcile the feries (which, however, was extremely regular) with the law of electric action. This harmony was probably difturbed by the force employed in raifing the filver wires. When more flexible filver threads were used, much was lost by diffipation from the roughnefs of the thread. We did not think of employing a fine flaxen thread moistened: but, indeed, an agreement was hardly to be expected; because theory teaches us, that the distribution of the redundant sluid in AB will be extremely different from the distribution of the redundant matter in DF, till the plates come very near each other. The accumulation in AB depends greatly on the law of distribution, being less (with any degree of redundancy) when the fluid is denfer near the centre of the plate. Other circumstances concurred to disturb this trial; but the theory was abundantly confirmed by the experiment, which shewed the strong attraction arifing from the accumulation This was fo great, that although the plates were only three inches in diameter, and the glass pane was 1/3 of an inch thick, and the threads deviated about 18 degrees from the perpendicular-it required above an ounce weight, hung on the wire EN, to separate the plates from the glass.

The experienced electrician need not be told, that by bringing the two ends of a bent wire in contact with the two plates (first touching DF with it) discharges the apparatus, and causes the plates to drop off from the pane. But he may farther observe, that if there be attached to each end of the discharging wire a downy feather, and if he first bring the end near the plate DF, and observe the seather to be not at all, or but a very little, affected, and if he then bend round the other end toward the plate AB, both feathers will immediately stretch out their fibres to the plates, and cling fast to them, long before the discharging spark is seen. This is a fine proof of the process of discharge, which begins by the induction of electricity on the ends of the

discharging wire; first, negative electricity on the end that approaches A, and, in the same instant, opposite electricities at D and the adjoining end of the wire.

The following observation of Professor Richmann of Beautiful St Petersburgh (the gentleman who fell a facrifice to rad infin electrical studies by a thunder stroke from his apparative expertus) is extremely instructive and amusing. Let a glass of the strong st pane be coated on both fides, and furnished with a small Richman electrometer attached to the coatings. It is represented as if seen edgewise in fig. 30. Let it be charged positively (that is, by redundancy) by the coating AB, while DF communicates with the ground. The electrometer A a will fland out from the plate, and Dd will hang down close by its coating, as long as DF communicates with the ground. But as the electricity gradually diffipates by communication to the contiguous air, the ball a will gradually, but very flowly, fall down. We may judge of the intensity of the remain. ing electricity by the deviation of the electrometer, and we may conceive this deviation divided into degrees, indicating, not angles, but intensities, which we conceive as proportional to the redundancy or deficiency which occasion them.

If we take away the communication with the ground, we shall observe the ball a fall down very speedily, and then more flowly, till it reach about half of its first elevation. The ball d will at the same time rise to nearly the same height; the angle between the two electrometers continning nearly the same as at first. When d has ceased to rife, both balls will very flowly descend, till the charge is lost by diffipation. If we touch DF during this descent, d will immediately fall down, and a will as fuddenly rife nearly as much; the angle between the electrometers continuing nearly the fame. Remove the finger from DF, and a will fall, and d will rife, to nearly their former places; and the flow defcent of both will again continue. The fame thing will happen if we touch AB; a will fall down close to the plate, and d will rife, &c. And this alternate touching of the coatings may be repeated some hundreds of times before the plate be discharged. If we suspend a crooked wire v mu, having two pith balls v and u from an infulated point m above the plate, it will vibrate with great rapidity, the balls striking the coatings alternately; and thus reftoring the equilibrium by steps. Each stroke is accompanied by a spark.

All these phenomena are not only consequences of Theory the theory, but their measures agree precisely with theit. computations deduced from the formulæ in n° 22, 23, 24, accommodated to the case by means of no 135 and 136, as we have verified by repeated trials. But it would occupy much room to trace the agreement here, and would fatigue fuch readers as are not familiarly conversant with fluxionary calculations. The inquifitive reader will get full conviction by perufing Æpinus's Essay, Appendix i. A very distinct notion may be conceived of the whole process, by supposing that in a minute AB lofes Toth of the unbalanced redundancy actually in it, and confequently diminishes as much in its action. It will be proved afterwards, that the diffipations in equal times are really in proportion to the fuperficial repulfions then exerted. We may also suppose, that the action of the redundant fluid, or redundant matter, in either coating, on the external fluid contiguous to it, is to its action on the fluid contiguous to

Discharge; how it is effected.

the other coating in the constant proportion of 10 to n. We select this proportion for the simplicity of the computation. Then the difference of these actions is always to it. This is also an exact supposition in some particular case, depending on the breadth of the coating

and the thickness of the pane.

Now, let the primitive unbalanced repulsion between AB and the contiguous fluid of the electrometer be 100, while DF communicates with the ground. The ball a will stand at 100; the ball d will hang touching DF. Then a, by lofing toth, retains only 90, and would fink to 90°: But as this destroys the equilibrium on the other fide, fluid will enter into DF, so as to reduce the deficiency inth. Therefore nine degrees of fluid will enter; and its action on a will be the same as if oths of 9, or 8,1 had been restored to AB. Therefore a will rife from 90 to 98,1; or it will fink in one

minute from 100 to 98,1.

But if we have cut off the communication of DF with the ground, this quantity of fluid cannot come into DF; and the quantity which really comes into it from the air will be to that which escapes from A as the attraction on the fide of DF to the repulsion on the fide of AB. By the diminution of the repulsion in the and the want of o degrees of fluid in DF to balance it, DF acquires an attraction for fluid, which may be called 9. Therefore, fince toth of the primitive repulsion of AB has difficated 10 measures of fluid in the minute, the attraction of DF will cause it to acquire inth of 9, or 0,9, from the air in the fame minute. At the end of the minute, therefore, there remains an unbalanced attraction for fluid = 8,1; and confequently an unbalanced repulsion between the redundant matter in DF, and that in the ball d. Therefore d will rife to 8,1. But a cannot now be at 98,1; because DF has not acquired 9 measures of sluid, but only of the of one measure. Therefore a, instead of rising from 90 to 98,1, will only rife to 90 + 10ths × 10ths; that is, to 90,81.

At the close of the minute, therefore, a is at 90,81, and d is at 8,1, and their distance is 98,91. In the next minute, AB will lose to the remaining unbalanced electricity of that fide, and DF will now acquire a greater proportion than before; because its former unbalanced attraction gets an addition equal to 28ths of the loss of AB. This will make a larger compensation in the action on a, and a will not fall fo much as before. And because in the succeeding minutes the attraction of DF for fluid is increasing, and the repulfion of AB is diminishing, the compensation in the action on a, by the increased attraction of DF, continues to increase, and the descent of a grows continually flower; confequently a time must come, when the repulsion of AB for fluid is to the attraction of DF for it, nearly in the proportion of 10 to 9. When this state obtains, d will rife no more; because the receipt of fluid by DF, being now on the loss by AB, it will exactly compensate the additional attraction of DF for fluid, occasioned by that loss. The next loss by AB not being fo great, and the next receipt by DF continuing the same, by reason of its undiminished attraction, there will be a greater compensation in the action on a, which will prevent its descending so fast; and there will be more than a compensation for the ad- posed non-conductor of that cause is demonstrated, and

ditional attraction of DF for fluid: that is, the fluid which has now come into DF will render it, and also the ball d, less negative than before; and therefore they will not repel so strongly. Therefore d must now defcend. It is evident, that fimilar reasons will still subfift for the flow descent of a, and the slower descent of d, till all redundancy and deficiency are at an end.

This maximum of the elevation of d happens when a has descended about one-half of its elevation; that is, when the unbalanced repulsion of AB is reduced to about one half. For if one half of the unbalanced fluid be really taken out of AB, and if DF can get no supply whatever, it must acquire an attraction corresponding to oths of this; and if the fupply by the air be now opened to it, things will go on in the way already described, till all is discharged.

This account of the process is only an approximation; because we have supposed the changes to happen in a defultory manner, as in the popular way of explaining the acceleration of gravity. The rife of d is not at an end till the attraction of DF for fluid is to the

repulsion of AB as 19 to 20.

But if we interrupt this progress in any period of it, by touching DF, we immediately render it neutral, and d falls quite down, in confequence of receiving a complete supply of shuid. But this must change the ftate of AB, and cause it to rise of the descent of As a and d were nearly at an equal height before DF was touched, it is plain that a will rife to nearly twice its present height; after which, the same series of phenomena will be repeated as foon as the finger is removed from DF.

If, instead of touching DF, we touch AB, the same things must happen; a must fall down, and d must rife to nearly twice its present height, and all will go on as before, after removing the finger. Laftly, if instead of allowing either fide to touch the ground alternately, we only touch it with a fmall infulated body, fuch as the wire with the balls v and u, the ball attached to the fide touched finks, till the electricity is shared between the coating and the wire with balls. The ball attached to the other coating rifes 70 ths of the finking of the first ball. The crooked wire ball is now repelled by the coating which it touched, and the other ball is brought near to the other coating, and must be attracted by it, because the electricities are opposite. This operation evidently tends to transfer the redundant fluid by degrees to the fide where it is deficient. It needs no explanation. We shall only mention a thing which we have always observed, without being able to account for it. The vibration of the wire acquires a certain rapidity, which continues for a long while, and fuddenly accelerates greatly, and immediately afterwards ceases altogether.

This pretty experiment of Professor Richmann will be found very instructive; and will enable us to understand the operation of the electrophorus, and to see the great miltake of those who say that it is perfectly

fimilar to a discharged glass plate.

Thus, then, we fee, that all the classes of phenomena, connected with attraction and repulsion, are precise tion edifianly fuch as would refult from the action of a fluid foti demon. constituted. The complete undiminished action of the strated. cause of those phenomena on the other side of the inter-

Franklin

all explanation by the mechanical action of material elastic atmospheres of variable density must be abandoned, and the infinitely fimpler explanation by the attractive and repulsive forces of the fluid itself must

be preferred.

So happily does the Franklinian theory of politive and negative electricity explain the phenomena, when a fuitable notion is formed of the manner of action of this fluid. We cannot but think that this is attained, when, to the general doctrine of Æpinus, we add the specification of the law of action, so fully verified by the experiments of Mr Coulomb, which are in the hands of the public; and are of that simple nature, that any careful experimentor can convince himself of their accuracy (See no 144.). We may therefore proceed with some confidence, and apply this doctrine even to cases where experiment does not offer itself for proof.

Dr Franklin affirms that electric fluid cannot be mistaken in thrown into one side of the coated pane unless it be Supposing abstracted from the other; and that therefore the charthat a char-ged glass contains no more than it did before charging. We indeed find, that we cannot charge the infide, if the contains its outfide do not communicate with the ground. He quantity of proves it also by saying, that if a person, when insulated, discharges a glass through his own body, he is not found electrified: And he infers, as a necessary confequence of this, that a feries of any number of jars may be charged by the same turns of a machine, if we make the outfide of the first communicate with the infide of the fecond, and the outfide of the fecond with the intide of the third; and so on; and the outside of the last communicate with the ground. Having made the trial, and having found that more turns of the machine were necessary, he attributes this to dissipation into the air by the communication. But our theory teaches us otherwife. We learn from it, that the redundant matter in the plate DF is less than the redundant fluid in AB, in the proportion of n-1 to n; and therefore the redundant fluid in the overcharged fide of the next plate is no greater. The charge or redundancy in the

mth jar of the feries will therefore be $\frac{n-1}{n}$ m. Thus,

if n, or the charge of the 1st jar, be 60, the charge of the 10th jar will be nearly 51. Although a coated plate cannot be charged, unless one of the coatings communicate with the ground, it may be electrified as much as one of the coatings can be alone. And this is feen in our attempt to charge it: For as foon as we attempt to electrify one fide, the other is electrified also; for it gives a spark, which no unelectrified body will do. Also, when we discharge a jar by an insulated discharger, we always leave it electrical in the same way with the body from which it was charged. If a man is not found electrified after having discharged a jar through his own body, it is owing to the great furface of his body, which reduces the simple electrification of a side of the jar to a very infignificant and infensible quantity.

Wilcke (and we believe Franklin before him) main-Mistake of tains, that when the jar has been charged, by connecting one fide with the prime conductor and the other with the rubber, it is neutral and inactive on both fides. But this is not so; and a slight reflection might have convinced them that it cannot be so: if it were, the jar could not be discharged. Each side, while connected with the machine, must be in the condition of the part with which it is connected, and in a disposition to take or give. If the trial be carefully made, it will be found to be equally affive on both fides; and the discharging rod, having down on its ends, will shew this in an unequivocal manner, and shew that its condition differs in this respect from that of a jarcharged in the ordinary way. It is in the maximum state of Richmanu's plate, described in n° 156. when d rises no more.

In discharging a jar A, if instead of the outside com-Charge.

municating with the infide by a wire, we make it com-jar by municate with the infide of a fecond jar B, while the discharge outfide of B is made to communicate with the infide of another, A, we shall find B charged by the discharge of A; and that the discharge of A is not complete, the charge 2' always remaining, whatever may have been the mag-

We may infer from this experiment, that when a Important shock is given to a number of persons, a, b, c, &c. we inserem are not to conclude, that the fluid which comes into the deficient fide of the jar is the same which came out of the redundant fide. The whole, or perhaps only a part, of the moveable fluid in the person a goes into b, replacing as much as has passed from b into c, &c. Indeed, where the canal is a slender wire, we may grant that great part of the individual particles of fluid which were accumulated on the infide of the jar have gone into the outside. Perhaps the quantity transferred, even in what we call a very great discharge, may be but a fmall proportion of what naturally belongs to a body. This may be the reason why a charge will not melt more than a certain length of wire. Mr Cavendish ascribes this to the greater obstruction in a longer wire; but this does not appear so probable. A greater obstruction would occasion a longer delay of the transference; and therefore the action of the same quantity would be longer continued. He proves, that a metal wire conducts many hundred times faster than water; yet, when water is diffipated by a discharge, it is found to have actually conducted a much greater proportion of the whole charge. We afcribe it chiefly to this, that, in a short wire, the quantity transferred exceeds the whole quantity belonging to the wire.

It is furely needless to prove that the theory of the Levden Leyden phial is the same with that of the coated pane. phial like The only difference is, that we are not so able to tell coated the disposition of the accumulated fluid, and the evacu-pane. ated matter, in every figure. When the phial is of a globular form, and of uniform thickness, with an exceedingly finall neck, we then know the disposition more accurately than in a plate. The redundant fluid is then uniformly distributed. If we could insure the uniformity of thickness, such a phial would be an excellent unit for measuring all other charges by; but we can neither infure this (by the manner of working glass), nor measure its want of uniformity: whereas we can have mirror plate made of precifely equal thickness, and measure it. This, therefore, must be taken

And here we remark, that this gives us the most perfect of all methods for comparing our theory with Excellent experiment. We must take two plates, of the same verifying glass and the same thickness, but of different dimen-the theen sions of coated furface. We must charge both by very long conducting wires on both fides, and then meafure

how often the charge of the one is contained in the other. Mr Cavendish has given an unexceptionable method of doing this independent of all theory. As it applies equally to jars, however irregular, we shall

take it altogether.

When a jar is charged, observe the electrometer connected with it, and immediately communicate the charge to another equal jar (the perfect equality being previoully ascertained by the methods, which will appear immediately). Again note the electrometer. This immediately). Again note the electrometer. will give the elevation, which indicates one-half, independent of all theory. Now electrify a jar, or a row of equal jars, to the same degree with the first, and communicate the charge to a coated mirror plate, discharging the plate after each communication, till the electrometer reaches the degree which indicates one-half. This shews how often the charge of the plate is contained in that of the jar or row of jars.

Let the charge of the plate be to that of the jars as x to 1. Then, by each communication, the electricity is diminished in the proportion of 1+x to 1. If m communications have been made, it will be reduced in the proportion of $1+x^m$ to 1. Therefore $1+x^m$ = 2, and $1 + x = {}^{m}\sqrt{2}$, and $x = {}^{m}\sqrt{2} - 1$.

When x is small in proportion to 1, we shall be very near the truth, by multiplying the number of communications by 1,444, and subtracting 0,5 from the product. The remainder shews how often the charge of

the plate is contained in that of the jars, or $\frac{1}{x}$.

Thus may the perfect equality of two jars be afcertained; and the one which exceeds, on trial, may be reduced to equality by cutting off a little of the coating. An electrician should have a pair of small jars or phials so adjusted. It will serve to discover in a minute or two the mark of one-half electricity for any electrometer, and for any degree; as also for meafuring jars, batteries, shocks, &c. much more accurately than any other method: because such phials, constructed as we shall describe immediately, may be made io neutral, and fo retentive, that the quantity which diffipates during the handling becomes quite infignificant in proportion to the quantity remaining; whereas, in all experiments with electrometers, constructed with the most curious attention, the dissipations are great in proportion to the whole, and are capricious.

It was chiefly by this method that the writer of this article, having read Mr Cavendish's paper, compared the measures given by experiment with those which refult from an action in the inverse duplicate ratio of the distance. When the charges were moderate, the coincidence was perfect; when the charges were great, the large plates contained a little more. This is plainly owing to their being less disposed to dissipate from the

We may now follow with fome confidence the pracax s for tical maxims deducible from the theory for the construction of this accumulating apparatus. The theory prescribes a very conducting coating, in close and uninterrupted contact: It prescribes an extensive surface, and a thin plate of idio-electric substance. Accordingly all these are in fact attended by a more powerful effect. Metal is found to be far preferable to water, which was first employed, having been suggested by the

original experiments of Gray, Kleist, and Cunæus. A continuous plating is prescribed, in preserence to some methods commonly practifed; fuch as filling the jar with brass dust, or gold leaf, or covering its surface with filings fluck on with gum water, or coating the infide with an amalgam of mercury and tin. This last appears, by reflection from the outfide, to give a very continuous coating; but if we hold the jar between the eye and the light, we may perceive that it is only like the covering with a cobweb. Yet there are cales where these imperfect coatings only are practicable, and some rare ones where they are preferable. In the Hint for medical exhibition of electricity, where the purpose in-medical extended is supposed to require the transfusion of a great hibition of quantity of the electric fluid, any thing that can dimi- electricity. nish the irritating smartness of the spark is desirable. This is greatly effected by those imperfect coatings. Small shocks, which convey the same quantity of sluid with the sharp pungent and alarming spark from a large furface, are quite foft and inoffentive, greatly refembling the spasmodic quivering, sometimes felt in the lip or eye-lid, and will not alarm the most fearful patient.

Close contact of the metallic coating is observed to How to increase the effect of the charge. But it is also found, prevent the that it greatly increases the risk of bursting the glass bursting of by fpontaneous discharge through its substance. An jars by high experienced electrician (we think it is Mr. Brook on a charges. experienced electrician (we think it is Mr Brookes of Norwich) fays, that fince he has employed paper covered with tinfoil, with the paper next the glass, instead of the foil itself, he has never had a jar burit; whereas the accident had been very frequent before. The theory justifies this observation. Paper is an imperfect conductor, even when foaked with flour paste; and the transfusion, though rapid, is not instantaneous nor defultory, but begins faintly, and swells to a maximum. It operates on the glass, like gradual warming instead

of the sudden application of great heat.

Mr Cuthbertson, an excellent artist in all electrical ap- Very curiparatus, and inventor of the best air-pump, has made a ous obsercurious observation on this subject. He says that he vation by has uniformly observed, that jars take a much greater Mr Cuthcharge (nearly one-third), if the infide be confiderably damped, by blowing into it with a tube reaching to the bottom (Nicholfon's Journal, March 1799).—We must acknowledge, that we can form no diffinct conception of what Mr Cuthbertson calls an undulation of the elastic atmosphere. We do not know whether he means that the atmosphere is actually undulating as water, or as air in the production of found, its parts being in a reciprocating motion; or whether he only means that this atmosphere consists of quietcent strata, alternately denser and rarer. Nor can we form any notion how either of these undulations contributes to the explosion, or prevents it. We are really but very imperfectly acquainted with that part of the science which should determine the precise accumulation that produces the defultory transference. We mentioned one necessary confequence of the action inverfely as the square of the distance, which has some relation to this question, viz. that a particle, making part of a spherical surface, is twice as much repelled when it has just quitted the furface as when it made part of it, provided its place be immediately supplied. And another circumstance has been frequently mentioned, viz. that a greater, and perhaps much greater, force is necessary for enabling a

particle of fluid to quit the last series of particles of a sufficient border unconted for preventing a spontonethe folid matter than for producing almost any constipation. But we are not certain that thefe circumstances are of sufficient influence to explain the whole of the event. Valeant quantum valere possint. Yet we are of opinion that Mr Cuthbertson has affigned the true cause, namely, the imperfect coating of the inside of the glass. When we come to the explanation of the escape of electricity along imperfect conductors, we hope that it will appear, that the disposition to escape must be greatly diminished by a charge, which disposes the fluid fo, that in no place the constipation is remarkably greater than in another part very near it, and the denfity changes everywhere flowly.

Best forms

With respect to the form of the coated glass, the for jars, &c. theory prescribes that which will occasion such a diffribution of the electric fluid as shall make its repulsion for the fluid in the canal which connects it with the prime conductor as little as possible. In this respect, it would feem that a plate is the best, and a globe the worst: but if both are very thin, the difference cannot be considerable. Our experience, however, seems to indicate the opposite maxim as the most proper. We have uniformly found a globe to be far preferable to a plate of the same thickness, and that a plate was generally the weakest form. It must be owned, that we have not yet been able to ascertain by the theory what is the exact distribution of the redundant fluid in a plate. In a sphere, it must be uniformly spread over the furface. We must also ascribe part of the inferiority of the plate to its greater tendency to diffipation from the edges. If a plate be coated in a star-like form, with slender projecting points, we shall observe them luminous in the dark, almost at the beginning of the accumulation; and the plate will discharge itself by these points, over the uncoated part, before it has at tained any confiderable strength. Those forms are least exposed to this deterioration which have the least circumference to the same quantity of surface. We have always found, that a square coating will not receive a more powerful charge without exploding than a circular one of the same breadth, although it contains a fourth more furface; and this although any visible escape from the angles be prevented by covering the outline with a very narrow, but long neck, is the most retentive. But it is very difficult to coat the infide of fuch a veffel. The balloons used in chemical distillations make excellent jars, and can be easily coated internally when the neck will admit the hand. The thinnest of tinfoil may be used, by first pasting it on paper, and then applying it either with the foil or the paper next the glass. It should be cut into gussets, as in the covering of terrestrial globes; and they should be put on overlapping about half an inch. The middle of the bottom is then coated with a circular piece. The great bottles for holding the mineral acids are also good jars, but inferior to the balloons, because they are very thick in the bottom, and for fome distance from it. A box of balloons contains more effective furface than an equal box of jars of the same diameter and height of coating.

The most compendious battery may be made in the ous battery following manner: Choose some very slat and thin panes of the best crown glass, coat a circle (a b c d),

ous discharge; let each of them have a harrow slip of tinfoil a reaching from the coating to the edge on one fide, and a similar slip c leading to the opposite edge on the other fide. Lay them on each other, fo that the flips of two adjoining plates may coincide. Connect all the ends of these slips on one side together by a slip of the same foil, or a wire which touches them all. Then, connecting one of these collecting slips with the prime conductor, and the other with the ground, we may charge and discharge the whole together. If the panes be round, or exact fquares, we may employ as few of them together as we please, by setting the whole in an open frame, like an old-fashioned plate-warmer; and then turning the fet which we would employ to-gether at right angles to the reft. This evidently detaches the two parcels from each other. This battery may be varied in many ways; and if the whole is always to be employed together, we may make it extremely retentive, by covering the uncoated border of the plate with melted pitch, and, while it is foft, preffing down its neighbour on it till the metallic coatings touch. For greater variability this may be done in parcels of the whole.

On the fame principle, a most compendious battery Anothe may be made by alternate layers of tinfoil and hard varnish, or by coating plates of very clear and dry Muscovy glass. But these must be used with caution, lest they be burst by a spontaneous discharge; in which case we cannot discover where the flaw has happened. They make a furprising accumulation, without shewing any vivid electricity.

We have made a very fine electric phial for carry- Portal ing about, by forming tin-plate (iron plate tinned) into jar. fomewhat of a phial shape, with a long neck. We then covered this with a coating of fine fealing wax, about 10th of an inch thick, quite to the end of the neck, and coated the fealing wax, all but the neck, with tinfoil. It is plain that the fealing wax is the coated idio electric, and that the tin-plate phial ferves for an inner coating and wire. The diffipation is almost nothing if the neck be very small; and it only requires a little caution to avoid burfting by too high a charge. Even this may be prevented by coating the fealing wax with fealing wax. Of all forms, therefore, a globe, so near to the end of the neck, that a spontaneous discharge must happen before the accumulation is too

It is well known that the discharge happens when Import the discharging balls are at a considerable distance from each other; therefore only as much is discharged as discharge corresponds to that distance. This is one cause of the refiduum of a discharge which sometimes is pretty considerable. Some experiments require the very utmost force of the charge. It is therefore proper to make the discharge as close and abrupt as possible. But the most rapid approach that we can make of the discharger is nothing in comparison with the velocity with which the fluid feems to fly off, and will therefore have but small influence in making a more instantaneous and complete discharge. Theory points out the following method: Let a very thick plate of glass (half an inch), of several inches diameter, be put between the discharging balls, which should, in this case, be small, and let these balls be firongly preffed against it by a spring. While the (fig. 31.) in the middle of both furfaces, so as to leave charge is going on, a very small part of the glass plate,

round the points of contact, will receive a weak and useless charge; but this will not hinder the battery from acquiring the same intensity of charge. When this is completed, let the intervening glass plate be briskly withdrawn. The discharge will begin with an intensity which is unattainable in the ordinary manner of pro-

ceeding.

Much has been faid of the lateral explosion. It appears, that in some of the prodigious transferences of electricity that have taken place in the discharge of great furfaces through wires barely fufficient to conduct them, flashes of light are thrown off laterally; but the most delicate electrometer, it is faid, is not affected. The fact is not accurately narrated; we have always observed a very delicate electrometer to be affected. The passage of fuch a quantity of fluid is almost equivalent to the co-existence of it in any given section of the wire; but it remains there for so short a time, that, acting as an accelerating force, it cannot produce a very fensible motion. It is like the discharging a pistol ball through a sheet of paper hanging loosely. It goes through it with-

out very fenfibly agitating it.

It has fometimes appeared to us probable, that, by means of this lateral explosion, the direction of the current may be discovered. Let the jar ab (fig. 32.) be isre discharged by a wire acdeb, interrupted at cd by the coating of a very thin plate of tale; let the coating also be very thin. There must be fome obstruction to the motion, which must cause the fluid to press on the sides or furfaces of the coating, just as the obstruction to the motion of water in a pipe (arising from friction, or even from material obstacles in the pipe) causes the water to press on the sides of the pipe. Therefore if a wire ** connect the other coating with the ground, we fhould expect that fluid will be expelled along this wire, and a charge be given to the plate of talc. Now whether the course in this apparatus be from b to a, or. from a to b, if any charge be acquired by cd, it will probably be positive in cd, and negative in $\times s$; for it is electric fluid that is supposed to pass: therefore we should always have one species of electricity, whether a has been charged by glass or by fealing wax: and this species will indicate which is positive. We have said "probably"—for it is not impossible that it may be otherwise. If the abstraction at d be supposed more powerful than the supplying force at c, the same obflruction may perhaps keep the plate c d in an absorbing flate, just as water descending in a vertical pipe, into which it is pressed by a very small head of water in the cistern, instead of pressing the sides of the pipe, rather draws them inwards, as is well known. This seems, at any rate, an interesting experiment; for we must acknowledge, that there still hangs a mysterious curtain before a theory which deduces fo much from the prefence of a substance which we have never been able to exhibit alone, and where we do not know when it abounds and when it is deficient. It is like the phlogiston of Stahl, or the caloric of Lavoisier. It will be proper to use the thinnest plate of tale to be charged, and to connect it with another coated plate of half the diameter, or lefs, in order to increase the accumulation. It feems by no means a desperate

The theory of coated glass now explained, might have been treated with more precision, and the formulæ

deduced in the beginning of this article might have been employed for stating the sum total of the acting forces, and thus demonstrating with precision the truth of the general refult; and indeed it was with fuch a view that they were premifed: but they would have been confiderably complicated in the prefent case; for however thin we suppose the tinfoil coatings to be, it is evident from n 92, &c. that each coating will confift of three strata; of which the two outermost are active, and must have their forces stated, and the statement of the force of each stratum would have consisted of three terms. This would have been very embarrassing to some readers; and the force of the conclusion would not, after all, have been much more convincing than we hope the above more loofe and popular account has

We have hitherto confidered the non-electric coat-Does the ings only, and have not attended to what may chancecharge reto obtain in the substance of the coated electrics them side in the felves. May not part, at least, of the redundant fluid coatings or be lodged in one superficial stratum of the glass? or, if glass? it do not penetrate it, may it not adhere to the furface, and drive off from the other furface, or stratum, a part of what naturally adheres to it? Till Dr Franklin's notions on the subject became prevalent, no person doubted this. The electric was supposed to contain or to accumulate in its furface all the electricity that we know. But the first suggestion of Dr Franklin's experiments certainly was, that the electric plate or veffel acted merely as an obstacle, preventing the fluid from flying from the body where it was redundant to that where it was deficient. It is therefore an important question in the science, whether the glass or electric concerned in these phenomena serve any other purpose besides the mere prevention of the redundant sluid from

flying to the negative plate?

Now it appears, at the very first, that this is the cafe. It is in the For if a glass be coated only on one side, and be elec-glass. trified on that fide, we obtain a strong spark from the other fide by bringing the knuckle near it: and this may be obtained for some time from one spot of that furface; and, after this, we get no more from that spot; but get sparks, with the same vivacity, and in the same number, from any other fpot that is opposite to the coating on the other fide. In this manner we can obtain a succession of sparks from every inch of surface opposite to the coating, and from no other part. But what puts this question beyond all doubt is, that if we now lay a metal coating on the furface from which the sparks have been drawn in this manner, and make a communication between the two metallic coatings, by means of a bent wire, we obtain a perfect discharge, To complete the proof, we need only observe, that this experiment succeeds whether the glass has been electrified by excited glass or by excited sealing wax. Therefore the coated surface may receive the electric sluid by the coating, as we see plainly that it is abstracted by the coating. The use of the coatings may be nothing. more than than to act as conductors to every part of the furface of the electric. None of these thoughts escaped the penetrating and fagacious mind of Dr Franklin. He immediately put it to the test of experiment; and, laying a moveable metallic coating on both furfaces, he found the glass charge perfectly well. He lifted off the coatings; which operation was accompanied by

flashes of light between the metallic coverings and the glass from which he separated them. Having removed the coatings, he applied others, completed the circle, and obtained a perfect discharge, not distinguishable from what he would have obtained from the first coat-

177 Charged glass acquires redundant and deficient strata.

Thus was it demonstrated, that the glass plate itself acquired by charging a redundant stratum on one side, and a deficient stratum on the other side; and we now fee, at once, the reason why the accumulation turns out greater than what is determined by the theory. The distance between the redundant and deficient stratum is less than the thickness of the glass; and this, perhaps, in an unknown proportion.

This precious experiment of Dr Franklin was repeated by every electrician, and varied in a thousand ways. No philosopher has carried this research farther than Beccaria; and he has given ground for a most important discovery in the mechanical theory, namely, that the charged glass has several strata, of inconceivable thinnefs, alternately redundant and deficient in electric fluid; and that by continuing the electrifica. tion, these strata penetrate deeper into the glass, and probably increase in number. We have not room here to give even an account of his experiments, and must refer the philosophical and curious reader to that part of his valuable Treatise where he treats of what he calls vindicating or recovering electricity; as also to a paper by Mr Henly in Phil. Trans. for 1766, giving account of experiments on Dutch plates by Mr Lane. The general form of the experiment is this. He puts two plates together; he coats the outer furfaces, and charges and discharges them as one thick plate. Their inner touching furfaces are found strongly electrical after the discharge, having opposite electricities, and changing these electricities, by repeated separations and replacings, in a way feemingly very capricious at first fight, but which the attentive reader will find to be according to fixed laws, and agreeably to the supposition that the strata gradually shift their places within the glass, very much resembling what we observe on a long glass rod which we would render electric by induction. In this case, as was observed in no 57. there are obferved more than one neutral point, &c.

Mr Cavendish endeavours to give us some notion of the disposition of the fluid in the substance of the glass in the following manner: Having separated the coated plate from the machine and from the ground, suppose a little of the redundant fluid in B & D (fig. 33.) equal to the fluid wanting in E : \(\varphi \) F. If we now suppose all the redundant fluid to be lodged in $b^{\beta S}d$, and $e \in f$ to hold all the redundant matter, and the two coatings to be in their natural state, a particle p, placed in the middle of the surface b d, will be nearly as much attracted by $c f \varphi$ as it is repelled by $b \varphi \delta d$ (exactly so if the plates were infinitely extended); and if the coating be removed, keeping parallel and opposite to the furface that it quits, there will be very little, if any, tendency to fly from the glass to the coating: there will rather be some disposition in the fluid to quit the coating and fly to the glass; because the repulsion of $b \beta \beta d$ is more diminished than the attraction of $e f \varphi$ (n° 42.). But the difference will be very small indeed. (N. B. the refult would be very different if electric ac-

tion followed a different law. Were it as $\frac{1}{d^3}$, the coating

would be much overcharged; and were it as $\frac{1}{d}$, it would be very much undercharged). Now the fact is, that when the coating is carefully removed, it is poffessed of very little electricity, not more than may reafonably be supposed to run into it by bringing away one part before another. It is impossible to keep it mathematically parallel.

Hence we may conclude that the greatest part of the redundant sluid is lodged in the glass if the plates be thin, and the redundant fluid bear but a small proportion to the natural quantity. Similar reasoning shews that the greatest part of the deficiency is in the other fide of the glass; and that therefore the coatings are very nearly in their natural state, and mcrely ferve

the purpose of conducting.

We have employed coatings of confiderable thick. ness, having holes through them, opposite to which was some gold leaf of the heaviest sort, and almost free of cracks. We have examined the state of the bottom of those pits in Mr Coulomb's manner, and always found

them void of electricity.

Thus we learn that glass, and probably all other e- Conject lectrics, acquire redundant and deficient strata as well as about the the most perfect conductors, at the same time that they bursting may be impervious to the fluid; and we get some mode are. of conceiving how the rupture happens by a strong charge. This may very probably happen when the strata have formed, in alternate order, so deep in the glass, that a stratum, in which the fluid is crowded close together, may become contiguous to one deprived altogether of fluid. We cannot, however, fay with confidence, what should be the effect of this state of things; or of one constipated stratum coming in contact with another.

This view of the condition of charged glass explains (we think) feveral phenomena which feem not well understood by electricians.

The residuum of a discharge is frequently owing to Several a charge extending beyond the coating, where the ac-phenom tion is confiderably irregular, or different from what it explains would be if the plates were infinitely extended. This outline charge is taken up by the coated part after a very little while, and may again be discharged. But it also frequently arises from another stratum (much thinner, as it will always be) than the exterior one, coming to the furface some time after the first discharge, and being now in a condition for being discharged. It explains the sparkling that is perceived in fuccession between the parts of a jar that is coated in spots, during the charge, and the very fensible residuum of the charge of fuch a veffel. It explains the phenomena of Beccaria's Electricitas Vindex (fee Electricity, Encycl. § 48.), and the great difference that may be found in the different kinds of glass in this respect. It explains the great difference between the fensation occasioned by a spark from a perfectly conducting surface of conside. rable extent, and that occasioned by a shock, which conveys the same quantity of fluid accumulated in a fmall furface of glass. The discharge of the first is almost instantaneous, while that of the last requires a fmall moment of time, and is therefore less defultory

and abrupt. The one is pungent and flartling; but the other is foster in the first instant, and swells to a maximum. Therefore, in the medical employment of electricity, when the purpose is to be effected by the transfusion of a great quantity of electric fluid, we should recommend very small shocks from a very large furface of coated glass, very faintly electrified, in place of strong sparks. Patients of irritable constitutions are frequently alarmed by the quickness and pungency of ftrong sparks: but if the balls of Lane's shock-meafurer be fet so close as to give four or five shocks in each turn of a feven inch cylinder, the shocks are not even difagreeable. The balls should be made of fine capelled filver: in which case, the furface will never be hurt by the greatest discharge; whereas the discharge of four square feet of coated glass will raise such a roughness on the surface of brass as will cause it to foutter, and destroy entirely the regularity of the expenditure of fluid. The same confideration should make us prefer a jar coated internally with amalgam. This cobweb coating gives a greater foftness to the shock. Lastly, we fee why a powerful and permanent electricity was not produced in the tube filled with melted fealing wax, and treated as mentioned in no 101. The redundancy and deficiency intended to be produced could only be superficial. And because the wax cooled by degrees from the surface to the axis, and the wax is a conductor while liquid, it must have taken a charge at last; and therefore must appear but faintly electrical.

This account of the state of charged glass promises us some affistance in our attempts to conceive what passes in the excitation of glass by friction. It appears from Beccaria's experiments, that the redundant fluid is lodged in the same manner in both cases; for by rubbing one fide of a glass tumbler, while points were presented to the opposite surface, and were connected with a wire that communicated with the ground,

he gave it a powerful charge.

It is observed, that when the laminæ of a piece of luid Muscovy glass are separated, by pulling them asunder ex. without inferting any infrument between them, they are electrical when separated; one being positive, and the other negative. Must we not conclude from this, that when conjoined they were in the state of charged glass? If we take this view of it, a body may contain a prodigious quantity of electric fluid without exhibiting any appearance of it. Mr Nicholfon found, by a very fair computation from his experiments, that a cubic inch of tale, when split into plates of 0,011 of an inch in thickness, and coated with gold leaf, gave a shock equal to the emptying 45 conductors, each seven inches in diameter and three feet long, electrified fo that each gave a spark at nine inches distance. Now, the whole of this-was moveable fluid, and no more than what the talc contains when unelectrified : for no more comes into the positive side than goes out of the negative side. Nay, there is no probability that the quantity moveable in our experiments bears a confiderable proportion to the natural quantity. The quantity of moveable fluid in a man's body is therefore very great: and Lord Mahon is well authorised to say, that the sudden displacing of this quantity in a returning stroke, which has been occasioned by a discharge of a cloud in a very distant place, is fully adequate to the production of the most violent effects. But his Lordship has not attend-SUPPL. Vol. I. Part II.

ed to the circumstance, that no such displacement can happen. The accumulation that can be made in the human body is only superficial; and therefore, altho' the whole fluid of a man's body may change its place, it will not change it with the rapidity that feems neceffary for the violent effects of electricity, except in the very points of communication with the furrounding

We have now feen in what fense the idio electrics may be faid to be impervious to the electric fluid. It is moved in them only to very fmall and imperceptible distances. When a considerable stratum is discharged, the fluid does not come from the extremity of it to the point of discharge through the glass, but through the coating. And when alternate strata of redundant sluid and redundant matter are formed, the particles in each shift their places very little, moving perpendicularly to the stratum.

Even this degree of obstruction has been denied by The imperi fome very active electricians, who have multiplied ex-meability periments to prove that the fluid paffes freely through of electrics class, and that the theory of coated electrics is retail, denied by glass, and that the theory of coated electrics is totally some. different from what Franklin imagines. Mr Lyons of Dover has published a numerous list of singular experiments, which he has made with this view, with much trouble, and no fmall expence. 'They may all be reduced to this: A wire is brought from the outside of a phial, charged by the knob, and terminates in a sharp point at a small distance from a thin glass plate (it is commonly introduced into a glass tube, having a ball at the end, and the point of the wire reaches to the centre of the ball); and another wire is connected with the discharging rod, and also comes very near (and frequently close) to the other fide of the glass, opposite to the pointed wire. With this apparatus he obtains a discharge; and therefore says, that the glass is permeable to electricity. But he does not narrate all the circumstances of the experiment. We have repeated all of them that have any real difference (for most of them are the same fact in different forms), and we have obtained discharges: But they were all very incomplete, except when the glass was perforated, which happened very frequently. The discharge was never made with a full, bright, undivided spark, and loud fnap; but with sputtering, and trains of sparks, continued for a very fensible time; and the phial was never deprived of a considerable part of its charge: and (which Mr Lyons has taken no notice of) the glass is found to be charged, negative on the fide connected with the positive side of the phial, and positive on the other. This charge was communicated to the glass over a pretty considerable surface round the points immediately opposite to the wires. This is quite conformable to the experiments of Dr Franklin and Beccaria, who charged a tumbler by grasping it with the hand, and presenting the inside to a point electrified by the prime conductor. The whole experiment is analogous to the one narrated in no 176.

We may conclude our observations on coated glass Bars touchwith mentioning a curious experiment. A flat stick of ed like fine fealing wax, warmed till it bent pretty readily, was magnets for rendered permanently electrical, with a positive and electricity. rendered permanently electrical, with a positive and negative pole, in a manner analogous to the double touch of magnets. A finall jar was taken, having a hemifphere on the end of its infide wire, and another on the

end of a stiff wire projecting from the outer coating, and then turned up parallel to the infide wire; fo that the two hemispheres flood equally high, and about three inches afunder. This jar was electrified fo weakly, as to run no risk of a spontaneous discharge. The flat faces of the two hemispheres were now applied to the flat fide of the fealing wax, and were moved to and fro along it, overpassing both ends about an inch with each hemisphere. The experiment was very troublesome; for the phial often discharged itself along the furface of the fealing wax, and all was to begin again. But, by continuing this operation till the fealing wax grew quite cold and hard, it acquired a very fensible electricism, which latted several weeks when kept with care; but still it was not much more sensible than that of the fealing wax, which congealed between two globes oppositely electrified.

After this application of the theory to the phenomena of coated glass, it will not be necessary to employ much time in its application to the electrophorus. The general propositions from no 14. to 2; and their companions in n° 38-43. will enable us to state with precifion (when combined with the law of electric action) the actions of every part of this apparatus; and confiderable affittance will be derived from a careful confideration of our analysis of Professor Richmann's experiment in no 156. But we must content ourselves with a general, popular view of these particulars, which may be fufficient for making us understand what will be the kind, and somewhat of the intensity, of the ac-

tion of its different parts.

The electrophorus consists of three parts. The chief part is the cake ABCD (fig. 34.) of some electric; fuch as gum lac, fealing wax, pitch, or other refinous composition. This is melted on some conducting plate, DCFE, and allowed to congeal; in which state it is found to be negatively electric. Another conducting plate GHBA is laid on it, and may be raifed up by filk lines, or any infulating handle. We shall call ABCD the CAKE, DCFE the SOLE, and GHBA the COVER.

The general appearances not having been fo scientifically classed in the article ELECTRICITY as could be wished, we shall here narrate them, very briefly, in a way more fuited to our purpole. In comparing the theory with observation, it will be proper to make all the three parts of considerable thickness, and of no great breadth. Although this diminishes greatly the most remarkable of the actions, it leaves them sufficiently vivid, and it greatly increases the smaller changes which are instructive in the comparison. The general

1. If the fole has been infulated during the congelation of the electric, till all is cold and hard, the whole is found negatively electric, and the finger draws a spark from any part of it, especially from the sole. If allowed to remain in this fituation, its electricity grows gradually weaker, and at last disappears: but it may be excited again by rubbing the cake with dry warm flannel, or, which is the best, with dry and warm cat or hare fur. If the cover be now fet on the cake by its infulating handle, but without touching the cover, and again separated from the cake, no electricity whatever is observed in the cover.

2. But if it be touched while on the cake, a sharp

pungent spark is obtained from it; and if, at the same time, the fole be touched with the thumb, a very fenfible shock is felt in the finger and thumb.

3. After this, the electrophorus appears quite inactive, and is faid to be dead; neither fole nor cover gi-

ving any fign of electricity. But,

4. When the cover is raifed to some distance from the cake (keeping it para!lel therewith), if it be touched while in this fituation, a fmart spark flies, to some distance, between it and the finger, more remarkably from the upper fide, and still more from its edge, which will even throw off foarks into the air, if it be not rounded off. As this diminishes the defired effects, it is proper to have the edge fo rounded. This spark is not so sharp as the former, and resembles that from any electrified conductor.

5. The electricity of the cover, while thus raised, is of the opposite kind to that of the cake, or is positive.

6. The electricity of the cover while lying on the cake is the same with that of the cake, or negative.

7. The appearances no 2, 3, 4, may be repeated for a very long time without any fensible diminution of their vivacity. The instrument has been known to retain its power undiminished even for months. This makes it a fort of magazine of electricity, and we can take off the electricity of the cake and of the cover as charges for separate jars, the cover, when raised, charging like the prime conductor of an ordinary electrical machine; and, when fet on the cake, charging it like the rubber. This caused the inventor, Mr Volta, to give it the name of ELECTROPHORUS.

8. If the fole be infulated before putting on the cover, the spark obtained from the cover is not of that cutting kind it was before: but the same shock will be felt if both cake and cover be touched together.

o. If the cover be again raised to a considerable height, the fole will be found electrical, and its electricity is that of the cake, and opposite to that of the cover.

10. After touching both cover and fole, if the cover be raifed and again fet down, without touching it while aloft, the whole is again inactive.

11. If both cover and fole be made inactive when joined, they shew opposite electricities when separated, the fole having the electricity of the cake.

12. If both cover and sole be made inactive when separate, they both shew the opposite to the electricity of the cake when joined.

Let us now attend to the disposition of the electrical Disposit fluid in the different parts of the instrument in their va-of thes rious fituations, and to the forces which operate mutually thercon between them. N. B. Experiments for examining this instrument are best made by setting the three plates vertically, supported on glass stalks, with leaden feet, to fleady them. A very small electrometer may be attached to the outer furfaces of the cover and fole.

If the extent of the plates were incomparably greater than their thickness, we may infer from no 92, &c. that the redundant fluid and matter would be disposed in parallel strata, and that the actions would be the same at all distances. But since this is not the case, the disposition of the fluid will be somewhat different; and whatever it is, the action of any stratum will be diminished by an increase of distance. The following description cannot be very different from the truth :

I. The cake grows negative by cooling; and if it

186 EleArophorus.

> Phenome. na thereof.

were alone, it would have a negative superficial stratum another gp BA, containing redundant sluid. But this on both fides, of greater thickness near the edges; and the fluid would probably grow denfer by degrees to the middle, where it would have its natural denfity. This disposition may be inferred from n° 92, 93, and 98. But it cools in conjunction with the sole, and the attraction of the redundant matter in the cake for the moveable fluid in the fole diffurbs its uniform diffusion in the sole, and causes it to approach the cake. And because this, in all probability, happens while the cake is still a conductor, the disposition of its sluid will be different from that described above, and the final dispofition of the fluid in the cake and fole will resemble that described in no 95, where the plates E and A represent the cake and sole. But because we do not know precisely the gradation of density, and aim only at general notions at present, it will be sufficient to confider the cake and sole as divided into two strata only; one redundant in fluid, and the other deficient, neglecting the neutral stratum that is interposed between them in each. The cake, then, confifts of a stratum A B ba A containing redundant matter, and a stratum ab CD containing redundant fluid: and the fole has a fratum DC n m containing redundant fluid, namely, all that belongs naturally to the space DCFE, and a stratum mn FE containing redundant matter. This may be called the PRIMITIVE STATE of the cake and fole; and if once changed by communication with unelectrified bodies, it can never be recovered again without some new excitement.

II If the fole be touched by any body communicating with the ground, fluid will come in, till the repulfion of the redundant fluid in the fole for a superficial particle y is equal to the attraction of the redundant matter in the cake for the same particle. What has been faid concerning infinitely extended plates, rendered neutral on one side, may suffice to give us a notion of the present disposition of the fluid in the sole. 'The under furface will be neutral, and the fluid will increase in density toward the surface DC. The sole contains more than its natural quantity of fluid, but is neutral by the balance of opposite forces. Let it now be infulated. This disposition of stuid may be called the common state of the electrophorus.

III. Let the cover GHBA be laid on it. The particle 2, at the upper furface of the cover, must be more attracted by the redundant matter in the stratum A B b a than it is repelled by the redundant fluid in the remoter strata; for the fluid in the cake is less than what belongs to it in its natural state, and therefore z is attracted by the cake. The redundant fluid which has come into the remote fide of the fole is less than what would faturate the redundant matter of the cake, because it only balances the excess of the remote action of this matter above the nearer action of the compressed fluid in the fole; and this smaller quantity of redundant fluid acts on z at a greater distance than that of the redundant matter in the cake. On the whole, therefore, the particle z, lying immediately within the furtace GH, is attracted; therefore some will move toward the cake, and its natural state of uniform diffusion through the cover will be changed into a violent state, in which it will be compressed on the surface AB, being abaracted from the furface GH. It will now have a stratum GgpH, containing redundant matter, and

will disturb the arrangement which had taken place in the fole, and had rendered it neutral on the under furface. We do not attend to the fluid in the cake, but confider it as immoveable, for any motion which it can get will be fo fmall, that the variations of its action will be altogether infignificant. The particle y, situated in that furface, will be more repelled by the compressed fluid in the stratum gpCA than it is attracted by the equivalent, but more remote redundant matter in GHpg. Fluid is therefore disposed to quit the surface EF, and the fole appears positively electric; very little indeed, if the cover be thin. All this may be obferved by attaching a small Canton's electrometer to the lower furface of the fole, or by touching the fole with the electrometer of fig. 8, and then trying its electricity by rubbed wax or glass.

IV. A particle of fluid z, placed immediately without the surface GH, will be more attracted by the deficient stratum GHpg and by ABba than it is repelled by the redundant strata beyond them, and the cover must be sensibly negative. This is the common flate of the whole inftrument after fetting on the cover. It is slightly positive on the lower surface of the sole, and much more fenfibly negative on the upper furface of the cover. A fmart spark will therefore be seen, between it and the finger, fluid will enter, till the attraction of the redundant matter in A B b a is balanced by the repulsion of the redundant fluid in DCFE.

V. A spark will now be obtained from the sole, be- Dead state, cause it was faintly positive before, and there has been added the action of the fluid which has entered into the cover. The fluid in the fole is therefore difposed to fly to any body presented to it. But when this has happened, the equilibrium at the furface GH is destroyed, and that surface again becomes negative, and will attract fluid, although the cover already contains more than its natural quantity. A' small spark will therefore be feen between the cover and any conducting body prefented to it. By touching it, the neutrality or equilibrium is restored at GH; but it is destroyed again at EF, which will again give a positive spark, which, in its turn, again leaves GH negative. This will go on for ever, in a series of communications continually diminishing fo as foon to become infensible, if the three parts of the electrophorus be thin. This makes it proper to make them otherwise, if the instrument be intended for illustrating the theory.

At last the equilibrium is completed at the surfaces GH and EF, and both are neutral in relation to furrounding bodies, although both the cover and fole contains more than their natural share of electric sluid. We may call this the NEUTRAL or DEAD state of the elec-

This state may be produced at once, instead of doing Charged it by these alternate touches of GH and E.F. If we flate. touch at once both these surfaces, we have a bright, pungent spark, and a small shock. It this be the object of the experiment, the state No IV. which gives occasion to it, may be called the CHARGED state of the electrophorus.

When the instrument has thus been rendered neutral in relation to furrounding bodies, it is plain that it may continue in this flate for any length of time without any diminution of its capability of producing the other

phenomena,

phenomena, provided only that no fluid pass from the cover to the cake. We do not fully understand what prevents this communication, nor indeed what prevents the rapid escape from an overcharged body into the air. This cause, whatever it be, operates here; and the best way of preventing the dislipation, or the abforption by the cake, is to keep the electrophorus with its cover on. It will come into this neutral state by diffipation from the fole, and abforption by the cover, in no very long time; and after this, will remain neutral, retaining its power with great obstinacy, especially if the cake and plates are very thin.

Charging or VI. If the cover be now removed to a calive state. parts of the apparatus will shew strong marks of electrical parts of the apparatus much redundant shuid, and must appear strongly positive, and will give a bright fpark, which may be employed for any purpose. It may be employed for charging a jar positively by the knob, if we just touch the cover with the knob. The fole will attract fluid, or be negative, although it contain more than its natural quantity of fluid, and it will take a spark. The sole therefore, in the absence of the cover, may be employed to charge a jar negatively by the knob. By touching it with the finger, or with the knob of a jar held in the hand, it is reduced to the common state described in No II.; and now all the former experiments may be repeated. We may call this the ACTIVE or the CHARGING state.

This state of the apparatus has caused it to get the name phorus not Elearophorus. Volta, its undoubted inventor, called it Elearoforo perpetuo; for it appears, as has been already obciry, but a ferved, to contain a magazine of electricity. The cover, when removed, will charge a jar held in the hand positively; and having done this fervice, it will charge a jar negatively when again fet on the cake. The fole, in the abfence of the cover, will charge a third jar negatively; and then, when the cover, after being touched, is fet down again, it will charge a fourth jar politively. It will not be difficult to contrive a simple mechanism, connected with the motion of the cover, which shall connect the joined parts with two jars, and shall connect them, when separated, with two others; and thus charge all the four with great expedition. All this is done without any new excitation of the electrophorus. But it is by no means a magazine of electricity which it gradually expends: it is a COLLECTOR of electricity from the furrounding bodies, which it afterwards imparts to others, and may be employed to discharge jars in the same gradual manner as to charge them.

VII. If the electrophorus is not infulated, a shock may still be obtained, by first touching the sole, and then, without removing the finger, touching the cover: but this will not be fo fmart as when the negative cover is touched at the same time that we touch the sole, more highly positive, than when it communicates with the ground. The difference must, however, be almost

imperceptible when the pieces are thin.

VIII. If the electrophorus is not infulated, the cover, when put on, will give a spark in the manner already mentioned, and it will be fomewhat stronger than when it is infulated; because the fluid is allowed

finger from it, touch the cover, we obtain a shock. This is evident from the theory. By this feries of alternate touches, the period of the electrophorus is completed. The electrophorus is charged, or rendered neutral, by touching the plates when joined; then, by touching both when separated, the whole is reduced to the common state. When separated, from being in the neutral state, they have opposite electricities, the sole thewing that of the cake. When brought together, each in the common state, they have opposite electricities, the cover shewing that of the cake.

IX. When, by long exposure to the air without its How it cover, the electrophorus has lost its virtue, it may be may be brought again into an active flate in a variety of ways. created, Its furface may be rendered negative by friction with dry cat or hare skin, or warm flannel. It may be rendered negative by fetting on it a jar charged negatively on the infide, and then touching the knob with any thing communicating with the ground. This is the most expeditious method, and will give it a high degree of excitation, if the jar be of fize, and if the electro-phorus be covered with a plate of tinfoil which comes into contact all over its surface. This however requires the previous charging of the jar; therefore it will be as expeditious and effectual to connect this surface with the rubber of an electrical machine. We had almost forgotten to remark, that the effects of bringing the cover edgewife to the cake follow clearly from the theory, as will appear to the attentive reader without

further explanation.

The electrophorus has been compared to a charged It is not plate of coated glass. It is true that it may be brought milar to charged into an external flate which very much refembles a page. charged pane; namely, when the cover, in its natural flate, is fet on the electrophorus in its natural flate; and accordingly it gives a shock, and the two exterior furfaces become neutral; but the internal constitution, and the acting forces, are totally and effentially different. The two coatings of the pane would not, when feparated, exhibit the appearances of the electrophorus; nor, when touched in their disjoined state, will they produce the same effects when joined. In the operation of coated glass, the conflant or invariable part, the glass is not the agent, it is merely the occasion of the action, by allowing the accumulation. In the electrophorus, the electric, which is the constant invariable part, is the agent producing the accumulation. The electrophorus is an original, and a very ingenious and curious electrical machine. Nothing has fo much contributed to fpread some general, though slight, acquaintance with the mechanical principles of electricity. The numerous dabblers in natural knowledge had been diverted from scientific pursuit by the variety of the singular and amufing effects of electricity, and had really attained very little connected knowledge. The effects of the electrophorus forced this knowledge on them; because no use can be made of it without a pretty clear conception of the disposition of the electricity, and the kind and intenfity of the actions. It is therefore most ungrateful in the experimenters who have attained better views, to attempt to rob Mr Volta of the real to escape from the sole, and does not obstruct the entry into the cover. If we then, without removing the fin- lar to those of Mr Symmer's stockings, or of Cigna's ger from the cover, touch the sole, nothing is selt; but plates, or of Franklin's charged or discharged glass if we first touch the sole, and, without removing the panes. And the attempt destroys itself: for it shews

the ignorance or inattention of its author; for the similarity is not real, as will appear clear to any person who will examine things minutely and scientifically, proceeding in this examination on suppositions similar to those which we employed in the analysis of Richmann's experiment. It was indeed in subserviency to this examination that we entered into the detail of that experiment, it being a simpler case. The accurate examination of Richmann's experiment requires the sluxionary calculus in its refined form. In the present question sive acting strata are to be considered, which renders the formulæ very complicated, and indeed intractable, unless we make the plates extremely thin; which, fortunately, is the best form of the instrument. We have completed this mathematical analysis; and the popular view here given is the result of that computation.

The electricians are no less obliged to Mr Volta for another machine, or instrument, from which the study of Nature's operations has derived, or may derive, immense advantages. We mean the CONDENSER, or COL-LECTOR of electricity. We refer to the article ELEC-TRICITY in the Encyclopædia for a description of the instrument, and some account of its effects and properties. The general effect is to render fenfible an accumulation or deficiency of electric fluid fo flight that it will not affect the most delicate electrometer; and it produces (at least in the opinion of Mr Volta) this effect, by employing for the fole of an electrophorus a body which is an imperfect conductor, fuch as a plate of well dried marble, or well dried, but not baked, wood; or even a conducting body, covered with a bit of dry taffety or other filk. Mr Volta, Cavallo, and others, who have written a great deal on the fubject, have attempted to shew how these substances are preferable (and they certainly are preferable in a high degree) to more perfect infulators: but not having taken pains to form precise notions of the disposition and action of the electric fluid in the fituations afforded by the instrument, their reasonings have not been very clear. We think that an adequate conception of the effentials of the proposed instrument may be acquired by means of the following confiderations:

Furnish the cover of an electrophorus with a graduated electrometer, which indicates the proportional degrees of electricity; electrify it positively to any degree, suppose six, while held in the hand, at some distance, right over a metal plate lying on a wine glass as an infulating stand, but communicating with the ground by a wire. Bring it gradually down toward the plate. Theory teaches, and we know it by experiment, that the electrometer will gradually fubfide, and perhaps will reach to 2° before the electricity is communicated in a spark. Stop it before this happens. In this state the attraction of the lying plate produces a compensation of four degrees of the inutual repulsion of the parts of the cover, by conflipating the fluid on its under furface, and forming a deficient stratum above. This needs no faither explanation after what has been faid on the charging of coated glass plates. Now we can suppose that the escape of the fluid from this body into the air begins as foon as electrified to the degree 6, and that it will fly to the lying plate with the degree 2, if brought nearer. If we can prevent this communication to the lying plate, by interposing an

electric, we may electrify the cover again, while so near the metal plate, to the degree 6, before it will stream off into the air. If it be now removed from the lying plate, the sluid would raise the electrometer to 10, did it not immediately stream off; and an electric excitement of any kind which could only raise this body to the degree 6 by its intensity, will, by this apparatus, raise it to the degree 10, if only copious enough in extent. If we do the same thing when the wire is taken away which connects the lying plate with the ground, we know that the same diminution of the electricity of the other plate caunot be produced by bringing it down into the neighbourhood of the lying plate (see no 134, &c. 151, &c.).

Here we fee the whole theory of Mr Volta's conden- Theory

fer. He seems to have obscured his conceptions of it therof. by having his thoughts running upon the electrophorus lately invented by him, and is led into fruitless attempts to explain the advantages of the imperfect conductor above the perfect infulator. But the apparatus is altogether different from an electrophorus, and is more analogous in its operations to a coated plate not charged nor infulated on the opposite side; and such a coated plate lying on a table is a complete condenser, if the upper coating be of the fame fize with the plate of the condenfer. All the directions given by Mr Volta for the preparation of the imperfect conductors shew, that the effect produced is to make them as perfect conductors as possible for any degree of electricity that exceeds a certain small intensity, but such as shall not suffer this very weak electricity to clear the first step of the conduit. The marble must be thoroughly dried, and even heated in an oven, and either used in this warm state, or varnished, so as to prevent the reabforption of moifture. We know that marble of slender dimensions, so as to be completely dried throughout, will not conduct till it has again become moist. A thick piece of marble is rendered to, superficially only, and still conducts internally. It is then in the best possible state. The fame may be faid of dry unbaked wood. Varnishing the upper furface of a piece of marble or wood is equivalent to laying a thin glass plate on it. Now this method, or covering the top of the marble, or of a book, or even the table, with a piece of clean dry filk, makes them all the most perfect condensators. This just view of the matter has great advantages. It takes away the mysterious indistinctness and obscurity which kept the instrument a quackish tool, incapable of improvement. We can now make one incomparably better and more fimple than any proposed by the very ingenious inventor. We need only the simple moveable plate. Let this be varnished on the under side with a moderately thick coat of the purest and hardest vernis de Martin, or coach-painters varnish; and we have a complete condenfator by laying this on a table. If it be connected by a wire with the fubstance in which the weak and imperceptible electricity is excited, it will be raifed (provided there be enough of it of that small intensity) in the proportion of the thickness of the varnish to the fourth part of the diameter of the plate. This degree of condensation will be procured by detaching the connecting wire from the infulating handle of the condenfer, and then raising the condenser from the table. It will then give sparks, though the original electricity. could not fensibly affect a flaxen fibre. It

It must be particularly noted, that it can produce this condenfation only when there is fluid to condenfe; that is, only when the weak electricity is diffused over a greater space than the plate of the condenser. In this way it is a most excellent collector of the weak atmospheric electricity, and of all diffused electricity. But to derive the same advantage from it in many very inte. resling cases, such as the inquiry into the electricity excited in many operations of Nature on small quantities of matter, we must have condensers of various fizes, fome not larger than a filver penny. To construct these in perfection, we must use the purest and hardest varnish, of a kind not apt to crack, and highly coercive. This requires experiment to discover it Spirit varnishes are the most coercive; but by their difference of contraction by cold from that of metals, they foon appear frosty, and when viewed through a lens, they appear all shivered: They are then useless. Oil varnishes have the requifite toughness, but are much inferior in coer-We have found amber varnish inferior to copal varnish in this respect, contrary to our expectation. On the whole, we should prefer the finest coach-painters varnish, new from the shop, into which a pencil has never been dipped: and we must be particularly careful to clear our pencils of moisture and all conducting matter, which never fails to taint the varnish. We scarcely need remark, that the coat of varnish on these small condenfers should be very thin, otherwise we lose all the advantage of their smallness.

Mr Cavallo has ingeniously improved Volta's condenser by connecting the moveable plate, after removal, with a smaller condenser. The effect of this is evident from no 130. But the same thing would have been generally obtained by using the small condenser at first,

or by using a still thinner coat of varnish.

. It will readily occur to the reader, that this inftrument is not inflantaneous in its operation, and that the application must be continued for some time, in order to collect the minute electricity which may be excited in the operations of nature. He will also be careful that the experiment be fo conducted that no useless accumulation is made anywhere elfe. When we expect electricity from any chemical mixture, it never should be made in a glass vessel, for this will take a charge, and thus may absorb the whole excited electricity, accumulating it in a neutral or infensible state. Let the mixture be made in veffels of a conducting fubstance, infulated with as little contact as possible with the infulating support; for here will also be something like a charge. Suspend it by filk threads, or let it rest on the tops of three glass rods, &c.

After this account of the Leyden plial, electrophorus, and condenfer, it is furely unnecessary to employ electricity. any time in explaining Mr Bennet's most ingenious and useful instrument called the doubler of electricity. The explanation offers itself spontaneously to any person who understands what has been faid already. Mr Cavallo has with industry fearched out all its imperfections, and has done fomething to remove them, by feveral very ingenious constructions, minutely described in his Treatife on Electricity. Mr Bennet's original instrument may be freed, we imagine, as far as feems possible, by using a plate of air as the intermedium between the three plates of the doubler. Stick on one of the plates three

very small spherules made from a capillary tube of glass,

or from a thread of sealing wax. The other plate being laid on them, rests on mere points, and can scarcely receive any friction which will diffurb the experiment. Mr Nicholfon's beautiful mechanism for expediting the multiplication has the inconveniency of bringing the plates towards each other edgewife, which will bring on a spark or communication sooner than may be defired: but this is no inconvenience whatever in any philosophical refearch; because, before this happens, the electricity has become very diftinguishable as to its kind, and the degree of multiplication is little more than an amusement. The spark may even serve to give an indication of the original intenfity, by means of the number of turns necessary for producing it. If the fine wires, which form the alternate connections in fo ingenious a manner, could be tipped with little balls to prevent the diffipation, it would be a great improvement indeed. An alternate motion, like that of a pump liandle, might be adopted with advantage. This would allow the plates to approach each other face to face, and admit a greater multiplication, if thought necessary.

One of the most remarkable facts in electricity is the Diffipation rapid diffipation by sharp points, and the impossibility of electric of making any confiderable accumulation in a body city from

which has any fuch, projecting beyond other parts of harp its furface. The diffipation is attended with many remarkable circumstances, which have greatly the appearance of the actual escape of some material substance. A stream of wind blows from such a point, and quickly electrifies the air of a room to fuch a degree, that an electrometer in the farthest corner of the room is affected by it. This diffipation in a dark place is, in many instances, accompanied by a bright train of light diverging from the point like a firework. Dr Franklin therefore was very anxious to reconcile this appearance with his theory of plus and minus electricity, but does not express himfelf well fatisfied with any explanation which had occurred to him. From the beginning, he faw that he could not confider the stream of wind as a proof of the efcape of the electric fluid, because the same stream is observed to issue from a sharp negative point; which, according to his theory, is not difperfing, but abforbing it. Mr Cavendish has, in our opinion, given the first fatisfactory account of this phenomenon.

To fee this in its full force, the phenomenon itself must be carefully observed. The stream of wind is plainly produced by the escape of fomething from the point itself, which hurries the air along with it; and this draws along with it a great deal of the furrounding air, especially from behind, in the same manner as the very slender thread of air from a blow-pipe hurries along with it the furrounding air and flame from a confiderable surface on all sides. It is in this manner that it gathers the whole of a large flame into one mass, and, at last, into a very point. If the smoke of a little rofin thrown on a bit of live coal be made to rife quietly round a point projecting from an electrified body, continually supplied from an electrical machine, the vortices of this fmoke may be observed to curl in from all fides, along the wire, forming a current of which the wire is the axis, and it goes off completely by the point. But if the wire be made to pass through a cork fixed in the bottom of a wide glass tube, and if its point project not beyond the mouth of the tube,

Cavallo's improvethereof.

202.

203 Bennet's doubler of

the afflux of the air from behind is prevented, and we have no stream; but if the cork be removed, and the wire still occupy the axis of the tube, but without touching the fides, we have the stream very distinctly; and smoke which rifes round the far end of the tube is drawn into it, and goes off at the point of the wire. Now it is of importance to observe, that whatever prevents the formation of this stream of wind prevents the diffipation of electricity (for we shall not say escape of electric fluid) from the point. If the point project a quarter of an inch beyond the tube, or if the tube be open behind, the stream is strong, and the dissipation so rapid, that even a very good machine is not able to raife a Henly's electrometer, standing on the conductor, a very few degrees. If the tube be flipped forward, so that the point is just even with its mouth, the diffipation of electricity is next to nothing, and does not exceed what might be produced by fuch air as can be collected by a fuperficial point. If the tube be made to advance half an inch beyond the point which it furrounds, the diffipation becomes insensible. All these facts put it beyond a doubt that the air is the cause, or, at least, the occafion of the diffipation, and carries the electricity off with it, in this manner rendering electrical the whole air of a room. The problem is reduced to explain how the air contiguous to a sharp electrified point is electrified and thrown off.

It was demonstrated in no 130, that two fpheres, connected by an infinitely extended, but slender conducting canal, are in electrical equilibrium, if their furfaces contain fluid in the proportion of their diameters. In this case, the superficial density of the sluid and its tendency to escape are inversely as the diameters (no 130.). Now if, in imagination, we gradually diminish the diameter of one of the spheres, the tendency to escape will increase in a greater proportion than any that we can name. We know, that when the prime conductor of a powerful table-machine has a wire of a few inches in length projecting from its end, and terminating in a ball of half an inch in diameter, we cannot electrify it beyond a certain degree; for when arrived at this degree, the electricity flies off in successive bursts from this ball. Being much more overcharged than any other part of the body, the air furrounding the ball becomes more overcharged by communication, and is repelled, and its place supplied by other air, not so much overcharged, which furrounded the other parts of the body, and is pressed forwards into this space by the general repulsion of the conductor and the confining preffure of the atmosphere; otherwise, being also overcharged, it would have no tendency to come to this place. Half a turn of the cylinder is sufficient to accumulate to a degree fufficient for producing one of these explohons, and we have two of them for every turn of the cylinder. A point may be compared to an incomparably smaller ball. The constipation of the fluid, and its tendency to escape, must be greater in the same un-measurable proportion. This density and mutual re-pulsion cannot be diminished, and must even be increafed, by the matter of the wire forming a cone, of which the point is the apex; therefore, if there were no other cause, we must see that it is almost impossible to confine a collection of particles, mutually repelling, and conftipated, as these are in a fine point.

But the chief cause seems to be a certain chemical

union which takes place between the electric fluid and a corresponding ingredient of the air. In this flate of Electricity constipation, almost completely surrounded by the air, mically the little mass of fluid must attract and be attracted with airs

with very great force, and more readily overcome the force which keeps the electrified fluid attached to the last series of particles of the wire. It unites with the air, rendering it electric in the highest degree of redundancy. It is therefore strongly repelled by the mass of conflipated fluid which succeeds it within the point. Thus is the electrified air continually thrown off, in a state of electrification, that must rapidly diminish the electricity of the conductor. Hence the uninterrupt. ed flow, without noise or much light, when the point is made very fine. When the point is blunt, a little accumulation is necessary before it attains the degree neceffary for even this minute explosion; but this is soon done, and these little explosions succeed each other rapidly, accompanied by a sputtering noise, and trains of bright sparks. The noise is undoubtedly owing to the atoms of the highly electrified fluid. These are, in all probability, rarefied of a sudden, in the act of electrification, and immediately collipse again in the act of chemical union, which causes a sonorous agitation of the air. This electrified air is thus thrown off, and its place is immediately supplied by air from behind, not yet electrified, and therefore strongly drawn forward to the point, from which they are thrown off in their turn. This rapid expansion and subsequent collapsing of the air is verified by the experiments of Mr Kinnerfly, related by Dr Franklin, and is feen in numberless experiments made with other views in later times, and not attended to. Perhaps it is produced by the great heat which accompanies, or is generated in the transference of electricity, and it is of the fame kind with what occasions the burlting of stones, splitting of trees, exploding of metals, &c. by electricity. The expansion is either inconfiderable, or it is fuccessively produced in very small portions of the substance expanded; for when metal is exploded in close veffels, or under water, there is but a minute portion of gazeous matter produced; and in the diffipation by a very fine point, sufficiently great to give full employment to a powerful machine, the stream of wind is but very faint, and nine-tenths of this has been dragged along by the really electrified thread of wind in the middle.

From a collation of all the appearances of electricity; we must form the same conception of the forces which operate round a point that is negatively electrified, not dispersing, but drawing in electric fluid. It is more completely undercharged than any other part of a body, and attracts the fluid in the furrounding air, and the air in which it is retained, with incomparably greater force. It therefore deprives the contiguous air of its fluid, and then repels it, and then produces a stream like

the overcharged point.

If a conducting body be brought near to any part of an overcharged body, the fronting part of the first is rendered undercharged; and this increases the charge of the opposite part of the overcharged body. It becomes more overcharged in that part, and fooner attains that degree of conflipation that enables the fluid to quit the superficial series of particles, and to electrify strongly the contiguous air. The explosion is therefore made in this part in preference to any other; and

the air thus exploded is strongly attracted by the fronting part of the other body, and must fly thither in preference to any other point. If, moreover, the fronting part of A be prominent or pointed, this effect will be produced in a superior degree; and the current of electrified air, which will begin very carly, will increase this disposition to transference in this way by rarefying the air; a change which the whole course of electric phenomena shews to be highly favourable to this transference, although we cannot perhaps form any very adequate notion how it contributes to this effect. This seems to be the reason why a great explosion and snap, with a copious transference of electricity, is generally preceded by a hissing noise like the rushing of wind, which swells to a maximum in the loud snap

208.

If two prominences, precifely fimilar, and electrified in the contrary way to the same degree, are presented to each other, we cannot fay from which the current should take its commencement, or whether it should not equally begin from both, and a general dispersion of air laterally be the effect; but such a fituation is barely possible, and must be infinitely rare. The current will begin from the fide which has some superiority of propelling force. We are disposed to think that this current of material electrified substance must suffer great change during its passage, by mixing with the current in an opposite electrical state coming from the other body. Any little mass of the one current must strongly attract a contiguous mass of the other, and certain changes should surely arise from this mixture. These may, in their turn, make a great change in the mechanical motions of the air; and, instead of producing a quaqua versum dispersion of air from between the bodies, as should result from the meeting of opposite streams, it may even produce a collapting of the air by the mutual strong attractions of the little masses. Many valuable experiments offer themselves to the curious inquirer. Two little balls may be thus presented to each other, and a fmoke may be made with rofin to occupy the interval between them. Motions may be observed which have certain analogies that would afford useful information to the mechanical inquirer. There must be fomething of this mixture of currents in all fuch transferences, and the most minute differences in the condition of a little parcel of the air may greatly affect the future motions. The most promising form of such experiment would be to use two points of the same substance, shape, and size, and electrified to the same degree in opposite senses.

Characteristic differences of positive and negative electricity

After all care has been taken to insure similarity, there remains one essential difference, that the one current is redundant in electric study, and the other descient. This circumstance must produce characteristic differences of appearance. And are there not such differences? Is not the pencil and the star of light a characteristic difference? And does not this well-supported fact greatly corroborate the opinion of Dr Franklin, that the electric phenomena result from the redundancy and desciency of one substance, and not from two distinct substances operating in a similar manner? For the distinction in appearance is a mechanical distinction. Motion, direction, velocity, are perceivable in it. Locomotive forces are concerned in it; but they are so implicated with sorces which probably resemble chemical affinities; hardly operating be-

yond contact, that to extricate their effects from the complicated phenomenon seems a desperate problem. There is some hitherto inexplicable chemical composition and decomposition taking place in the transference of electricity. Of this a numerous train of observations made fince the dawn of the pneumatic chemistry leaves us no room to doubt. The emersion or production of light and heat is a remarkable fign and proof. Now this takes place along the whole path of transference; therefore the process is by no means completed at the point from which the active caute proceeds; and although there be certain appearances that are pretty regular, they are still mixed with others of the most capricious anomaly. The zigzag form of the most condensed spark, totally unlike, by its sharp angles, to any motions producible by accelerating forces, which motions are, without exception, curvilineal, makes us doubt exceedingly whether the luminous lines which we observe are successive appearances of the same matter in different places, or whether they be not rather fimultaneous, or nearly fimultaneous, cornfcations of different parcels of matter in different places, indicating chemical compositions taking place almost at once; and this becomes more probable, when we reflect on what has been faid already of the jumbling of opposite currents; such mixtures should be expected. We have seen a darted flash of lightning which reached (in a direction nearly parallel to the horizon) above three miles from right to left; and it feemed to us to be co-existent; we could not fay at which end it began. The thunder began with a loud crack, and continued with a most irregular rumbling noise about 15 seconds, and seemed equal on both hands. We imagine that it was really a simultaneous fnap, in the whole extent of the spark, but of different frength in different places; different portions of the fonorous agitation were propagated to the ear in fuccession by the sonorous undulations of air, causing it to feem a lengthened found. Such would be the appearance to a person standing at one end of a long line of foldiers who discharge their firelocks at one instant. It will seem a running fire, of different strength in different parts of the line, if the muskets have been unequally loaded. It is inconceivable that this long zigzag spark can mark the track of an individual mass of electrified air. The velocity and momentum would be enormous, and would fweep off every thing in its way, and its path could not be angular. The fame must be afferted of the streams of light in our experiments. The velocity is fo unmeasurable that we cannot tell its direction. There may be very little local motion, just as in the propagation of found, or of a wave on the furface of water. That particular change of mutual fituation among the adjoining atoms which occasions chemical solution or precipitation may be produced in an instant, over a great extent, as we know that a parcel of iron filings, lying at random on the furface of quickfilver, will, in one instant, be arranged in a certain manner by the mere neighbourhood of a magnet. Is not this like the fimultaneous precipitation of water along the whole path of a discharge?

But fill there must be some cause which gives these simultaneous coruscations a situation with respect to each other, that has a certain regularity. Now the luminous trains (for they are not uniform lines of light) of almost continuous sparks which are arranged between

a politive and a negative point, seem to us to indicate emanation from the positive, and reception by the negative point. The general line has a confiderable refemblance to the path of a body projected from the pofitive point, repelled by it, and attracted by the negative point. This will appear to the mechanician on a very little reflection. If the curve were completely vifible, it would fomewhat refemble those drawn between P and N in fig. 35. PABN overpasses the point N, and comes to it from behind; Pab N lies within the other, and arrives in a direction nearly perpendicular to the axis; P a BN describes a straight line, and arrives in the direction PN. As the chemical composition advances; the light is difengaged or produced, and therefore the appearances are more rare as we advance farther in the direction in which they are produced; and there would perhaps be no appearance at all at the point where the motion ends, were it not that the few remaining parcels, where the compositions or decompofitions have not been completed, are crowded together at the negative point, incomparably more than in any other part of the track. We think that these considerations offer some explanation of the appearance of the pencil and star, which are so uniformly characteristic of the politive and negative electricities; but we fee many grounds of uncertainty and doubt, and offer it with due diffidence.

The curious figures observed by Mr Lichtenberg, ec- formed by the dust which fettles on a line drawn on ing the face of a mirror by the positive and by the negative knobs of a charged jar, are also uniformly characteristic of the two electricities. These are mechanical an -. distinctions, indicating certain differences of accelerating forces. We must refer the curious reader to Lichtenberg's Differtations in the Gottingen Commentaries; to the Publication of the Haerlem Society; to the Gotha Magazine; to Differtations by Spath at Alt dorff, and other German writers.

It only remains for us to take notice of the general ci. laws of the diffipation of electricity into the air, and along imperfect infulators. On this subject we have some valuable experiments of Mr Coulomb, published in the Memoirs of the Academy of Sciences of Paris for 1785.

These experiments were made with the assistance of an electrometer of a particular construction, which shall be described under the article Electrometer.

The general result of Mr Coulomb's experiments was, that the momentary diffipation of moderate degrees of electricity is proportional to the degree of electricity at the moment- He found that the diffipation is not fensibly affected by the state of the barometer or thermometer; nor is there any fenfible difference in bodies of different fizes or different substances, or even different figures, provided that the electricity is very weak.

But he found the diffipation greatly affected by the different states of humidity of the air. Saussure's hygrometer has its scale distinctly related to the quantity of water diffolved in a cubic foot of the air. The following little table shews an evident relation to this in the diffipation of electricity:

SUPPL. VOL. I. Part II.

Hygrometer.	Grains water in cubic foot.	Diffipation Jes		
69	· 6,197 · ·	minute.		
.75 • •	• 7,295	·		
87	· 8,045 · .	· 20·		

Hence it follows, that the diffipation is very nearly in the triplicate ratio of the moisture of the air. Thus if

$$\frac{60}{47}$$
 be confidered as $=\frac{7,197}{6,180}^m$ we have $m = 2,764$.
 $\frac{60}{29}$ - $=\frac{8,045}{6,180}^m$ gives $m = 2,76$.

$$\frac{6.0}{4.3}$$
 - - = $\frac{9,220}{6,180}$ gives $m = 3,61$.

Hence, at a medium, m = 3,40. We should have observed, that the ingenious author took care to separate this diffipation by immediate contact with the air, from what was occasioned by the inperfect infulation afforded by the supports.

It must also be remarked here, that the immediate Diminution object of observation in the experiments is the diminu of repulsion tion of repullion. This is found to be, in any given is double of ftate of the air, a certain proportion of the whole rethe diffipapullion at the moment of diminution; but this is double of the proportion of the denfity of the electric fluid; for it must be recollected, that the repulsions by which we judge of the diffipation are mutual, exerted by every particle of fluid in the ball t of Coulomb's electrometer, on every particle in the ball a. It is therefore proportional to the electric denfity of each; and therefore, during the whole diffipation, the denfities retain their primitive proportion; therefore, the diminution of the repulfion being as the diminution of the products of the densities, it is as the diminution of the Iquares of either. If therefore the density be represented by d, the mutual repulsion is representable by d2, and its momentary diminution by the fluxion of d^2 ; that is, by 2 d d, or 2 d × d. Now 2 $d \times d$ is to d^2 as 2 d is to d; and therefore the diminution of repulsion observed in our experiment bears to the whole repulsion twice as great a proportion as the diminution of density, or the quantity of fluid dissipated, bears to the whole quantity at the moment. For example, if we observe the repulsion diminished to, we

conclude that so of the fluid has escaped.

Mr Coulomb has not examined the proportion between the diffipations from bodies of different fizes. A great and a small sphere, communicating by a very long canal, have superficial densities, and tendencies to escape, inversely proportional to the diameters. A body of twice the diameter has four times the furface; and though the tendency to escape be twice as small, the furface is four times as great. Perhaps the greater furface may compensate for the smaller density, and the quantity of sluid actually gone off may be greater in a large sphere. This may be made the subject of trial.

It must be kept in mind, that the law of diffipation Diffipation afcertained by these experiments, relates to one given depends on state of the air, and that it does not follow that in the state of another state, containing perhaps the same quantity of the air. water, the diffipation shall be the same. The air is such

a beterogeneous and variable compound, that it may have very different affinities with the electric fluid. Mr Coulomb thought that he should infer from his numerous experiments, that the diffipation did not increase in the ratio of the cube of the water dissolved in the air, unless it was nearly as much as it could diffolve in that temperature. This indeed is conformable to general observation: for air is thought dry when it dries quickly any thing exposed to it; that is, when not nearly faturated with moisture. Now it is well known, that what is thought dry air is favourable to electricity.

The diffipation along imperfect infulators is brought 216 D.ffipation by imperfect infulators.

about in a way somewhat different from the manner of its escaping by electrifying the contiguous air and going off with it. It feems to be chiefly, if not folely, along the furface of the infulating fupport that the electricity is diffused, and that the diffusion is produced there chiefly by the moisture which adheres to it. It is not very easy to form a clear notion of the manner, but Mr Coulomb's explanation seems as satisfactory as

any we have feen.

Procedure thereof.

Water adheres to all bodies, Ricking to their furfaces. This adhesion prevents it from going off when electrified; and it is therefore susceptible of a higher degree of electrification. If we suppose that the particles of moisture are uniformly disposed along the furface, leaving spaces between them, the electricity communica. ted to one particle must attain a certain density before it can fly across the insulating interval to the next. Therefore, when fuch an imperfect conductor is electrified at one end, the electricity, in passing to the other, will be weakened at every step. If we take three adjacent particles a, b, c, of this conducting matter, we learn, from no 105, that the motion of b is fenfibly affected only by the difference of a and c; and therefore that the passage of electricity from b to c requires that this difference be superior or equal to the force necessary for clearing this coercive interval. Let a particle pass over. The electric denfity of the particle b of conducting matter is diminished, while the denfity of the particle on the other fide of a remains as before. Therefore some will pass from a to b, and from the particle preceding a to a; and so on, till we come to the electrified end of this imperfect infulator. It is plain from this confideration, that we must arrive at last at a particle beyond c, where the whole repulsion of the preceding particle is just fufficient to clear this interval. Some will come over, whose repulsion, now acting in the opposite direction, will hinder any fluid from supplying its place in the particle which it has quitted. Here the transference will stop, and beyond this the infulation is complete. There is therefore a mathematical relation between the infulating power and the length of the canal, which may be afcertained by our theory; and thus another opportunity obtained for comparing it with obfervation. That this investigation may be as timple as possible, we may take a very probable case, namely, where the infulating, or, to name it more graphically, the coercive, interval is equal in every part of the canal.

Let R be the coercive power of the infulator; that is, let R be the force necessary for clearing the coercive interval. Let a ball C (fig. 36.) be suspended by a filk thread AB, and let C represent the quantity of its redundant fluid; and let the density in the different points of the canal be as the ordinates AD, Pd, &c. of fome curve line D d B, which cuts the axis in B where the

thread begins to insulate completely. Let Pp be an element of the axis. Draw the ordinate pf, the tangent df F, and the normal d E, and fe perpendicular to P d. Let AC be = r, AP = x, P d = y. Then $Pp = \dot{x}$, and $de = -\dot{y}$. We have feen, that the only fenfible action on the particle of fluid in P is — (fee no 105), when the action of the redundant fluid in the globe on the particle P having the denfity y, is represented by $\frac{Cy}{(r+x)^2}$. Therefore we have $\frac{yy}{x} = \frac{y}{x}$

R, the coercive power of the thread. This is suppofed to be constant. Therefore $\frac{P d \times d e}{P p}$ is equal to fome constant line R. But P p, or f e : d e = P d: PE. Therefore the subnormal PE is a constant line. But this is the property of the parabola alone; and the curve of denfity D d B is a parabola, of which the parameter is 2 PE, or 2 R.

Cor. 1. The densities in different points of an im- Variation perfect infulator are as the fquare roots of their distance of deadly from the point of complete infulation: For P d: AD: the latter, = BP : BA.

2. The length of canal required for infulating dif-Length ferent densities of electricity are as the squares of the collary infulation densities. For $AB = \frac{AD^2}{2PE}$; and PE has been shewn $= \frac{AD^2}{2PE}$

to be a constant quantity. Indeed we see in the demonstration, that BP would insulate a ball, whose electric denfity is Pd, and BA: BP = AD²: Pd².

3. The length necessary for infulation is inversely as $Alfo = \frac{2D}{1}$ the coercive force of the canal, and may be represented 1 generally by $\frac{D^2}{R}$. For AB is $= \frac{DA^2}{2PE} = \frac{D^2}{2R}$.

Mr Coulomb has verified these conclusions by a very fatisfactory feries of experiments, by the affiftance of his delicate electrometer, which is admirably fuited for this trial. The subject is so interesting to every zealous student of electricity, that Mr Canton, Dr B. Wilfon, Mr Waitz, Wilcke, and others, have made experiments for chablishing some measure of the conducting powers of different fubftances. It was one of the first things that made the writer of this article suppose that electric action was in the inverse duplicate ratio of the distances: for, as early as 1763, he had found, that the lengths of capillary tubes necessary for infulation were as the fquares of the repulsions of the ball which they infulated. The mode of reasoning offers of itself, and the fluxionary expression of the infulating power,

viz. $\frac{d\dot{d}}{x}$ led immediately to a force proportional to $\frac{1}{x^{2}}$.

Numerous experiments were made, which we do not give here, because the public are already possessed of those of Mr Coulomb.

This discussion explains, in a satisfactory manner, the Explain operation of the condenfer, as described by Mr Volta. time The weak degrees of electricity, which are rendered voltage fufficiently fenfible by the infulation of the plate of dry denfat marble, are completely infulated by the perhaps thin stratum that has been fusficiently dried, while the rest conducts with an efficacy fufficient for permitting the accumulation.

217 Theory thereof

When

When we reflect on the theory now delivered, we fee that the formulæ determine the distribution of the fluid along an imperfect conductor in a certain manner, on the supposition that a certain determinate dose has been imparted to the ball: Because this dose, by diffufing itself from particle to particle of the conducting matter, will diffuse itself all the way to B, in fuch a manner that the repulsion shall everywhere be in equilibrio with the maximum of the coercive force of the infulating interval. But it must be farther noticed, that this refistance is not active, but coercitive, and we may compare it to friction or vifcidity. Any repulsion of electric fluid, which falls short of this, will not disturb the stability of the sluid spread along the canal, according to any law whatever. So that if AD represent the electric density of the globe, and remain constant,

any curve of density will answer, if $\frac{d}{x}$ be everywhere

lefs than R. It is therefore an indeterminate problem to affign, in general, the disposition of sluid in the canal. The density is as the ordinates of a parabola only on the supposition that the maximum of R is everywhere the same. And, in this case, the distance AB is a minimum: for, in other cases of density, we must have

 $\frac{d}{d}$ lefs than R. If, therefore, we vary a fingle element of the curve D d B, in order that the stability of

the fluid may not be disturbed, having d constant, we must necessarily have a larger, that dd may still be less

than R; that is, we must lengthen the axis.

Exp 1a-

We see also, that to ascertain the distribution in a conducting canal is a determinate problem; whereas, in imperfect conductors, it is indeterminate, but limited by the state of the sluid, when it is so disposed that in every point the action of the fluid is in equilibrio with the maximum of refistance. This confideration will be applied to a valuable purpose in the article MAGNETISM.

This doctrine gives, in our opinion, a very fatisfactory explanation of the curious observations of Mr sand Brookes and Mr Cuthbertson, mentioned in nº 167. namely, that damping the infide of a coated jar dimifad and namely, that damping the inflict of enables it to hold a mel d of nishes the risk of explosion, and enables it to hold a inci fing a higher charge. We learn here, that there is no denfity so great but that the least imperfect conductor will insulate it, if long enough; and that the coercive quality of an imperfect conductor may be conceived fo constituted from A towards B, that the densities shall diminish in any ratio that we please, so that the variation of denfity (the caufe of motion) may everywhere, even to the infulating point B, be very fmall. However great the constipation at the edge of the metallic coating may be, an imperfect conductor may be continued outward from that edge, and may be so constituted, that the conflipation shall diminish by such gentle gradations, that an explosion shall be impossible. An uniform dampness will not do this, but it will diminish the abruptness of the variation of density. The state of density beyond the edge of the coating of a charged jar, very clean and dry, may be represented by the parabolic arch Dia. This may be changed by damping, or properly dirtying (to use Mr Brookes's phrase), to D f B; which is evidently preferable. We

think it by no means difficult to contrive such a continuation of imperfectly conducting coating. Thus, if gold leaf can be ground to an impalpable powder, it may be mixed with an oil varnish in various proportions. Zones of this gold varnish may be drawn parallel to the edge of the coating, decreasing in metal as they recede from the edge. By fuch contrivances it may be poffible to increase the retentive power to a great degree.

This doctrine farther teaches us, that many precau- Cautions in tions must be taken when we are making experiments deducing from which meafures are to be deduced; and it points measures them out to the mathematician. In particular, when from expebodies, fupported by infulators, are electrified to a high degree, the fupports may receive a quantity of fluid, which may greatly diffurb the refults; and this quantity, by exerting but a weak action on the parts of the canal, may continue for a very long time, and not be removed but with great difficulty. In fuch cases, it will be necessary to use new supports in every experiment. Not knowing, or not attending to this circumstance, many erroneous opinions have been formed in fome delicate departments of electrical research.

Mr Coulomb's experiments on this fubject are chiefly valuable for having stated the relation between the intensity of the electricity, or, as he expresses it, the electric denfity, and the lengths of fupport necessary for the complete infulation. But, as the absolute intensities have all been meafured by his electrometer, and he has not given its particular scale, we cannot make much use of them till this be done by some electrician.

Mr Coulomb found, that a thread of gum lac was Infulating the most perfect of all infulators, and is not less than powers of ten times better than a filk thread as dry as it can be various made, if we measure its excellence by its shortness. In substances: a considerable number of experiments, he found that a thread of gum lac, of 1,5 inches long, infulated as well as a fine filk thread of 15 inches. When the thread of filk was dipped in fine fealing wax, it was equal to the pure lae, if fix inches long, or four times its length. If we measure their excellence by the intensities with which they infulate, lac is three times better than the dry thread, and twice as good as the thread dipped in fealing wax ; fo that a fibre of filk, even when included in the lae, diminishes its infulating power. We also learn, that the diffipation along thefe fubstances is not entirely owing to moisture condensed or adherent on their furfaces, but to a fmall degree of conducting power. We have repeated many of these experiments, and find that the conducting power of filk thread depends greatly on its colour. When of a brilliant white, or if black, its conducting power feems to be the greatest, and a high golden yellow, or a nut brown, feemed to be the beil infulators; doubtless the dyeing drug is as much concerned as the fibre.

Glass, even in its dryest stare, and in situations where moisture could have no access to it, viz. in vessels containing caustic alkali dried by red heat, or holding fresh made quicklime, appeared in our experiments to be confiderably better than filk; and where drawn into a flender thread, and covered with gum lac (melted), infulated when three times the length of a thread of lac; but we found at the fame time, that extreme fineness was necessary, and that it dislipated in proportion to the fquare of its diameter. It was remarkably hurt by having a bore, however fine, unless the bore could also

be coated with lac. Human hair, when completely freed from every thing that water could wash out of it, and then dried by lime, and coated with lac, was equal to filk. Fir, and cedar, and larch, and the rofe-tree, when fplit into filaments, and first dried by lime, and afterwards baked in an oven which just made paper become faintly brown, feemed hardly inferior to gum lac.

The white woods, as they are called, and mahogany, were much inferior. Fir baked, and coated with melted lac, seems therefore the best support when strength is required. The lac may be rendered less brittle by a minute portion of pure turpentine, which has been cleared of water by a little boiling, without femily increafing its conducting power. Lac, or fealing wax, diffolved in spirits, is far inferior to its liquid state by

These observations may be of use for the construction of electrical machines of other electrics than glass.

WE have now given a comparison of the hypothesis of Mr Æpinus with the chief facts observed in electricity, diverlified by every circumstance that seemed likely to influence the refult, or which is of importance to be known. We trust that the reader will agree with us in faying that the agreement is as complete as can be expected in a theory of this kind; and that the application not only feems to explain the phenomena, but is practically useful for directing us to the procedurcs which are likely to produce the effect we wish. Thus, should our physiological opinions suggest that copious transference of fluid is proper, our hypothesis points out the most effectual and the most convenient methods for producing it. We learn how to constipate the fluid in a quiescent state, or how to abstract as much of it as possible from any part of a patient; we can do this even in the internal parts of the body. We had once an opportunity of feeing what we thought the cure of a paralysis of the gullet. Electricity was tried, first in the way of sparks, and then small shocks taken across the trachea. These could not be tolerated by the patient. The furgeon wished to give a shock to the cosophagus without affecting the trachea. We recommended a leaden pistol bullet at the end of a ftrong wire, the whole dipped in melted fealing wax. This was introduced a little way, we think not more than three inches, into the gullet, which the palfy permitted. A very flight charge was given to it in a few feconds; and the first shock produced a convulsion in the muscle, and the second removed the disorder completely. Here the ball formed the inner, and the gullet the outer, coating of the little Leyden phial.

The theory

Notwithstanding the flattering 'testimony given by of Æpinus the great conformity of this doctrine with the phenomena, we still choose to present it under the title of a hypothesis. hypothesis. We have never seen the electric fluid in a separate state; nor have we been able to say in what cases it abounds, or when it is deficient. After what we have feen in the late experiments of that philanthropic philosopher Count Rumford on the production of heat by friction, we think that we cannot be too cautious on what grounds we admit invisible agents to perform the operations of Nature. We think that all must acknowledge that those experiments tend very much

to stagger our belief in the existence of a sluid fui generis, a fire, heat, caloric, or what we please to call it; and all will acknowledge, that no better proofs can be urged for the existence of an electric sluid.

Accordingly, many acute and ingenious persons have The rea rejected the notion of the existence of an electric fluid, of an electric and have attempted to shew that the phenomena pro-tric slui ceed, not from the presence of a peculiar substance, but denied. from peculiar modes; as we know that found, and fome concomitant motions and other mechanical appearances, are the refults of the elastic undulations of air; and as Lord Bacon and others have explained the effects of fire by elaftic undulations of the integrant particles of

tangible matter.

We have feen nothing, however, of this kind that Requifin appears to give any explanation of the motions, pref-for a jul fures, and other mechanical appearances of electricity, theory, We peremptorily require, that every doctrine which claims the name of an explanation, shall be perfectly confistent with the acknowledged laws of mechanism; and that the explanation shall confift in pointing out those mechanical laws of which the facts in electricity are particular instances. It is no difficult matter to prefent an intricate or complex phenomenon to our view, in fuch a form, that it shall have some resemblance to fome other complex physical fact, more familiar, perhaps, but not better understood. The specious appearance of fimilarity, and the more familiar acquaintance with the other phenomenon, dispose us to consider the comparison as a fort of explanation, or, at least, an illustration, and to have a fort of indolent acquiescence in it as a theory.

But this will not do in the present question: For we have here felected a particular circumstance, the observed motions occasioned by electricity, and called attractions and repulsions - a circumstance which admits of the most accurate examination and comparison with any explanation that is attempted. In fuch a case, a vague picture would speedily vanish into air, and prove to be

nothing but figurative expressions.

Many philosophers, and among them some respect. No advar able mathematicians, have supported the doctrine of tage is gall Du Fay, Symmer, Cigna, &c. who employ two fluids ed bythe as agents in all electrical operations. It must be grant hypothetis ed that there are some appearances unless the solution of two ed that there are fome appearances, where the explana-fluids. tion by means of two fluids feems, at first fight, more palpable and easier conceived. But whenever we attempt to obtain measures, and to say what will be the precise kind and degree of the action, we find ourselves obliged to affign to the particles of those shuids actuating mechanical forces precifely equivalent to those asfigned by Æpinus to his fingle fluid. Then we have to add some mysterious unexplained connections, both with each other and with the other particles of tangible matter. If we except Mr Prevost, in his Essai sur les Forces Magnetiques et Electriques, we do not recollect an author who has ventured to subject his system to first examination, by pointing out to us the laws of action according to which he conceives the particles influence each other. We shall have a proper opportunity, in the article MAGNETISM, to give this author's theory the attention it really merits. We venture to fay, that all the chemical theories of electricity labour under these inconveniences, and have acquired their influence merely from the inattention of their par-

tilans to the laws of mechanical motion, and require, in order to reconcile them with those laws, the adoption of powers similar to Æpinus's attractions and repulfons. Slight refemblances to phenomena, which stand equally in need of explanation, have contented the partifans of fuch theories, and figurative language and metaphorical conceptions have taken place of precise discussion. It would be endless to examine them all.

The most specious of any that we know was pubof ofessor licly read in the university of Edinburgh by the late Mr James Ruffel, Professor of natural philosophy; a perfon of the most acute discernment, and an excellent reafoner. It was delivered to his pupils, not as a theory, but as a conjecture, founded on Lord Kames's theory of spontaneous evaporation, which had obtained a very general reception; a conjecture, faid the Professor, founded on fuch refemblances as made a fimilarity of operation very probable, and was an incitement and direction to the philosopher to a proper train of experimental discussion. We say this on the authority of his pupils in the years 1767, 1768, and 1769, and of some notes in his own hand writing now in our possession.

Mr Russel considered the electrical phenomena as the results of the action of a substance which may be called the electrical fluid, which is connected with bodies by attractive and repulfive forces acting at a distance, and

diminishing as the distance increases.

Mr Russel speaks of the electric fluid as a compound of feveral others; and, particularly, as containing elementary fire, and deriving from it a great elasticity, or mutual repulsion of its particles. This, however, is different from the elafticity or mutual repulsion of the particles of air, because it acts at a distance; whereas the particles of air act only on the adjoining particles. By this constitution, bodies containing more electric fluid than the spaces around them repel each other.

The particles of this electric fluid attract the particles of other bodies with a force which diminishes by distance.

The characteristic ingredient of this fluid is ELECTRIcitr properly so called. This is united with the elastic fluid by chemical affinity, which Mr Russel calls elective attraction, a term introduced into chemistry by Dr Cullen and Dr Black. This extends to all distances, but not precifely by the same law as the mutual repulsion of the particles of the other fluid, and in general, it represses the repulsions of that sluid while in this state of composition. This electricity, moreover, attracts the partieles of other bodies, but with certain elections. Non-electric or conducting bodies are attracted by it at all distances; but electrics act on it only at very small and insensible diftances. At fuch distances its particles also attract each

By this conflitution, the compound electric fluid repels its own particles at all confiderable distances, but attracts at very small distances. It attracts conducting bodies at all distances, but non-conductors, only at very small distances. The phenomena of light and heat are confidered as marks of partial decomposition, and as proofs of the prefence of elementary fire in the compound: the smell peculiar to electricity, and the effect on the organ of taste, are proofs of decomposition and of the complex nature of the fluid.

Bodies (conductors) containing electric fluid, repel each other at confiderable distances, but, if forced very near, attract each other. Electrics can contain it only

in consequence of the electricity in the compound. Part of this electricity must be attached to the surface in a non-elastic state; because when it is brought so near as to be attracted, its particles are within the spheres of each other's action, and this redoubled attraction overcomes the repulsion occasioned by its union with the other ingredient; and the electric fluid is partly decomposed, and the electricity, properly so called, adheres to the surface of the electric, as the water of damp air adheres to a cold pane of gluss in our windows. Also, by this constitution, electric sluid may appear in two states; elastic, like air, when entire; and unelastic, like water, when partly decomposed by the attraction of electrics.

Electricity may be forced into this unelastic union by various means; by friction, which forces the electric fluid contained in the air into close contact, and thus occasions this decomposition of the sluid and the union of its electricity with the furface. This operation is compared by Mr Ruffel to the forcible wetting of some powders, such as lycoperdon, which cannot be wetted without forme difficulty and mechanical compression; after which it adheres to water throngly. It may be thus united in fome natural operations, as is observed in the melting and freezing of fome fubstances in contact with electrics; and it may be thus forced into union by means of metallic coatings, into which the electric fluid is forced by an artful employment of its mutual repulsions. This operation is compared to the condensation of the moisture of camp air by a cold pane of the window; and the evacuation of the other fide of the coated pane is compared to the evaporation of the moisture from the other side of the window pane, in consequence of the heat which must emerge from the condensed vapour. We find in the Profesior's notes above-mentioned many fuch partial analogies, employed to shew the students that fuch things are seen in the operations of Nature, and that his conjecture merits at. tention.

The intelligent reader will fee that the general refults of this constitution of the electric fluid will tally. pretty well with the ordinary electrical phenomena; and, accordingly, this conjecture was received with great fatisfaction. We remember the being much pleafed with it, as we heard it applied by Mr Ruffel's pupils, many of whom will recollect what is here put on record. But the attentive reader will also see, that all this intricate combination of different kinds of attraction and repulsion is nothing but mere accommodations. of hypothetical forces to the phenomena. How incomparably more beautiful is the fimple hypothetis of Æpinus, which, without any fuch accommodations, tallies so precisely with all the phenomena that have yet been observed? Here no diffinction of action is necesfary, and all the varieties are confequences of a circumstance perfectly agreeable to general laws; namely, that the internal structure of some substances may be such as obstructs the motion of the electric fluid through the pores-Nothing is more likely.

Several years after the death of the Scotch Pro-Hypothesis fessor in 1773, a theory very much resembling this of Mr de acquired great authority, being proposed to the phi-Luc. losophers by the celebrated naturalist Mr de Luc. This gentleman having long cultivated the ftudy of meteorology with unwearied affiduity and great fuccefs,

and having been so familiarly convenant with expansive fluids, and the affinities of their compounds, was dispor fed to fee their operations in almost all the changes on the furface of this globe. Electricity was too bufy an actor in our atmosphere to escape his particular notice. While the mechanical philosophers endeavoured to explain its effects by accelerating forces attracting and repelling, Mr de Luc endeavoured to explain them by means of the expansive properties of aeriform fluids and gases, and by their chemical affinities, compositions, and decompositions. He had formed to himself a peculiar opinion concerning the constitution of our atmofphere, and had explained the condensation of moisture, whether of steam or of damp aeriform sluids, in a way much more refined than the fimple theory of Dr Hooke, viz. folution in air. He confiders the compound of air and fire as the carrier of the water held in folution in damp air, and the fire as the general carrier of both the air and the moisture. Even fire is considered by him as a vapour, of which light is the carrier. When this damp air or steam is applied to a cold surface, fuch as that of a glass pane, it is decomposed. The water is attracted by the pane by chemical affinity, and attaches itself to the surface. The fire, thus set at liberty, acts on the pane in another way, producing the equilibrium of temperature, and the expansion of the pane. Acting in the fame manner on the moisture which chances to adhere to the other fide, in a proportion suited to its cal combination with the moisture, and fits it for uniting with the air on the other fide, or carries it off. Having read Mr Volta's theory of electric influences, by which that philosopher was enabled to give a scientific narration and arrangement of the phenomena of the electrophorus newly invented by himself, and which is called an explanation of those phenomena, Mr de Luc imagined that he faw a close analogy between those influences on the plates of the electrophorus and the hygroscopic phenomena of the condensation and evaporation of moisture. In short, he was struck with the resemblance between the condensation of moisture on one side of a glase pane, and its evaporation from the other; and the accumulation of electric fluid on one fide of a coated pane, and the abstraction of it from the other. Subsequent examination pointed out to him the same analogy between all other hygroscopic and electric pheno-

He therefore immediately formed a fimilar opinion concerning the electric operations. It may be expressed

briefly as follows:

The electrical phenomena are the operations of an expansive substance, called the electric fluid. This confifts of two parts: 1. Elearic matter, which is the gravitating part of the compound; and elearic deferent fluid, or carrying fluid, by which alone the electric matter feems to be carried from one body to another. The resemblance between the hygroscopic and electrical phenomena are affirmed to be *, # See Idees

1. As watery vapour or steam is composed of fire, the deferent fluid, and water, the gravitating part, fo \$,260, &c. electric fluid is composed of the electric deferent fluid, and electric matter.

2. As vapours are partly decomposed when too dense for their temperature, and then their deferent fluid becomes free, and shews itself as fire; so eledric fluid

that is too dense is decomposed, and its deferent fuid manifests itself in the phosphoric and stery phenomena of

3. As fire quits the water of vapour, to unite itself with a body less warm; so the electric deferent quits the electric matter, in part, to go to other bodies which have

proportionally less of it.

In this analogy, however, there is a distinction. Fire, in quitting the water in vapour, remains actuated by nothing but its expansive force; remains free, and extends itself till the equilibrium of temperature is restored; but the electric deferent, when difengaged from electric matter, in order to restore its peculiar equilibrium, is actuated by tendencies to distinct bodies, and acts by this tendency in thus restoring the electric equilibrium; and it is only in consequence of this tendency that it quitted the electric matter. This tendency is then directed to some body in the vicinity.

4. As the fire of vapour pervades all bodies, to restore the equilibrium of temperature, depositing the water; fo the electric deferent quits the electric matter, to restore the electric equilibrium in an instant, and for this purpose pervades all bodies, depositing on them the electric matter which it carried, but differently, according to

5. As fire and water, while composing vapour, retain their tendencies and affinities by which they produce the hygroscopic phenomena; so the ingredients of the electric temperature, it destroys their union, enters into chemi- fluid, even in their state of union, retain their tendencies and affinities, which produce the greatest part of the electric phenomena.

6. In particular, the electric matter retains its tendencies and affinities; and farther, the electric affinities are, like

the hygroscopic, without any choice.

Here, however, there is a farther distinction. The affinities of water respect only hygroscopic substances; but those of electric matter respect all substances, and therefore respect the common atmospheric fluids.

7. When fire quits the water of vapour, to form the equilibrium of temperature, it remains in the place where vapour most abounds, but is partly latent, not exerting its powers; so in the restoration of the equilibrium of the electric deferent among neighbouring bodies, those which have proportionally most electric matter also retain most deferent fluid, but in a latent state.

8. As two masses of vapour may be in expansive equilibrium (which others call balancing each others elasticity) although the vapours contain very different proportions of fire and water; fo two masses of electric stuid may be in expansive equilibrium, although one contains much more electric matter in the same bulk, provided that the electric deferent be a so more copious.

The chief distinction that mingles with these analogies is, that the affinity of water to hygroscopic subtlances operates only in contact, whereas electric matter tends to distant bodies; and these distances are very dif-

ferent in regard to different bodies.

Such is the refemblance which has appeared fo strong to Mr de Luc. It is evidently the same which furnished the conjecture to Mr Russel, and which he confidered mechanically, in order to explain the pheno nena of electric motions to students of mechanical philosophy. The only refemblance feems to us to appear in the condensation of moisture contained in damp air.

Mr de Luc, led by the habits of his former studies,

attempts

attempts to explain every thing by the relations which were most samiliar to him, affinities and expansive forces. Let us attend a little to the manner in which he explains one or two of the most general facts.

1. The conditions of conductors and non-conductors.

This diffinction depends on the differences in the tendency to distant bodies: there are great differences in these distances according to the nature of the bodies; and from this arife great differences of phenomena, independent of insulation or non-insulation, which are only the sensible distinctions of these classes of bodies. Electric matter tends to conductors at great distances; but having reached them, it does not adhere, and remains free to move round them, being dragged by the deferent fluid; but its tendency to non-conductors is only at fmall and infensible distances; and having come into contact, it adheres, and can no longer be dragged by the deferent fluid.

Hence the operation of conductors and non-conductors; and there is no other foundation for the notion of idioelectrics and non-electrics, or electrics by communication. A part of a non-conductor takes as much electric matter as it can from the fubflance furnishing it; but cannot communicate it to another part, except very flowly; therefore, to communicate it to the whole surface, we must cover it with a conductor (Surely this is a diflinction in the body, independent of the diffance of

mutual tendency!).

Hence, too, the property of non-conductors by which the electric fluid is benumbed (engourdi) or cramped; therefore we can accumulate a great deal in them; and it will remain long, being benumbed; and if it be determined to quit them at once, the current will be much more dense than when quitting an equal conducting furface.

Since conductors do not fix the electric fluid, it must circulate round them. It is urged to this motion by its expansive power, by which it would disperse from a body with inconceivable velocity, and perhaps the rapidity of its motion would decompose it, and cause some light to emerge; but it is at the same time impelled by its tendency to bodies. Thus, by these two forces, it runs to a conducting body, and must circulate round it as the planets do round the fun. In this circulation, if it come to any great projection, it cannot follow the outline, because so abrupt; it therefore flies off at all points and protuberances. It will be the more difficult to keep to an abrupt outline as the fratum in circulation is more copious or deeper, because a greater mass is with greater difficulty turned round a sharp angle: It is more inclined to escape if another body be near, and it immediately becomes a fatellite to that body.

Thus all bodies get a share of electric sluid, circulating round conductors, and benumbed or cramped in nonconductors. Bodies of this last class receive their portion by the air as hygroscopic substances receive their

water by the fire.

All the differences in the tendencies to bodies proceed from the electric matter. The deferent fluid follows other laws; namely, 1. Its tendency to all substances is greater than that of the electric matter to any one. 2. The tendency (and also that of the electric matter) is always from the body which contains most of it to that which contains leaft. 3. The body which contains

most of the one also contains most of the other. 4. The deferent fluid has a particular affinity (chemical) with the electric matter. 5. All these tendencies are lesfened by an increase of distance. 6. The electric matter, when composing electric fluid, has more or less expansive force as it is united to more or less deferent fluid.

Explanation of Charged Plates.

Mr de Luc fays (§ 286.), that his System was fuggested by Volta's Theory of Electric Influences. These (fays he) had been pretty well generalised before, but with little improvement to the science, till Mr Volta discovered a circumstance which, in his opinion, connected by a general theory many phenomena which had formerly no observed relation to any thing. This was, that when a body electrified positively brings a neighbouring body communicating with the ground into the negative state, its own positive electricity is weakened while it remains in that neighbourhood, but is recovered when the other body is removed. "Such is the diftinguishing law of Mr Volta's theory, which brings all the phenomena of electric influences under his theory, beginning with those of coated glass, which were formerly so obscure, because they were not referred to their true cause, &c.

"My System (Mr de Luc says) concerning the nature of the electric fluid explains the laws of Mr Volta's theory; and of confequence explains, like it, all the phenomena which it comprehends: but it reaches much farther, feeing that more general laws compre-

hend a greater number of phenomena.
"In the phenomena of coated glass, I plainly saw one of the procedures of watery vapour. Suppose a glass pane, moistened on both fides, and having the temperature of the furrounding bodies Suppose that warmer vapour comes to one fide. It is condenfed on the furface; that is, it is decomposed, the water adheres to the furface, and the fire penetrates the glafs, heats it, and increases the evaporation from the other fide, by entering into combination with the water, and carrying it off with it. More vapour is condensed on the fide A; more fire reaches the fide B, and carries off more water. But as this happens only because the fire also raises the temperature of the pane, it is evident. that the condensation on the side A, and the evaporation from B, must gradually slacken, and the maximum of accumulation in A, and of evaporation from B, will take place when the temperature of the pane is the fame with that of the hot vapour.

"The electrical phenomena of coated glass are perfeetly fimilar. The electric fluid reaches the fide A, is decomposed, and the electric matter is there benumbed and fixed. The deferent fluid penetrates the pane, and carries off the electric matter from the side B. This goes on, but flackens; and the maximum of accumulation and evacuation obtains when the fide A has acquired the same intensity of electricity with the charging machine. More is accumulated in A than is abstracted from B; because B is farther from the source. (he might have added, that part of the fire is expended in raising the temperature of the pane): but the accumulation is inactive, because the electric matter is benumbed and fixed. Though the electric matter is much diminished in B, yet the electric fluid in its coating has as much expansive force as that of the ground;

because

232.

because it has a surplus of deferent fluid. The absolute quantity of electric matter in both sides is somewhat

augmented."

This explanation of the Leyden phial comprehends the whole of Mr de Luc's theory; and the conflitution of the electric fluid, and its various affinities, expansive powers and tendencies, are all assigned to it in subserviency to this explanation, or deduced from those phenomena. As the author, in all his writings, claims some superiority over other naturalists for more general and comprehensive views, and for more ferupulous attention to precision and measurement, and particularly for more solicitude that no natural agent be omitted that has any share in the procedure, he surely will not be offended, although we should state such difficulties and objections as occur to us in the consideration of this System (as he chooses to call it) of electricity.

We wish that it had been expressed in the plain and precise language of mechanical and chemical science; for he reasons entirely from the nature of expansive forces, tendencies, and affinities. His language will appear to some readers, as it does to us, rather to express the conduct of intelligent beings, acting with choice, and for a purpose, than the laws of lifeless matter. His account would have been less agreeable, it is true, but more instructive, and less apt to be mistaken. Metaphorical language is feldom ufed without the risk of metaphorical conceptions; and the reader is very apt to think that he has acquired a notion of the fubject. while he is really thinking of a thing of a different nature. We apprehend that a great deal of this happens in this instance, and that when the narration is stripped of its figurative language, it will be found without that connection and analogy which it feems to poffefs.

We also wish that the explanation had been derived from some well-established principle. The whole of it is professedly founded on a refemblance between the phenomena of electricity and some things faid of watery vepour; but these are not the phenomena of watery vapour, but Mr de Luc's hypothesis (he will pardon us the term, which we prefer to fystem) concerning watery vapours. We do not think it philosophical to explain one hypothesis by another. Our illustrious countrymen Bacon and Newton, disapproved of this practice; and their rules of philosophifing have still currency among philosophers. Explanation, in our pinion, is the pointing out some acknowledged general fact in nature, and shewing that the particular phenomenon is an example of it. We do not fee this in Mr de Luc's explanation; because we do not see the facts in the case of watery vapours to which the phenomena of electricity are faid to have a refemblance. The phenomena we mean are chiefly the motions, and the transferences of the powers producing fuch motions; we do not speak of the light, and some other phenomena, because Mr de Luc does not speak of them in this explanation. We shall even admit the transference as a phenomenon, although we do not fee any substance transferred: but we fee a power of producing certain motions, where that power did not formerly appear; and the appearance of this power is all the anthority adduced, even by Mr de Luc, for the transference. We must now

add, that the electric phenomena, which Mr de Luc calls like the phenomena of watery vapour, are all fuppositions; and that therefore the explanation is a system of suppositions, framed so as to be like the system of watery vapour. For Mr de Luc will grant, that, on the one hand, we see nothing like the water in the electric phenomena; and, on the other hand, there is nothing in watery vapour like the motions of the electrometers, which are the only PHENOMENA from which Mr de Luc professes to reason.

We also fear that the very curious experiments of Count Rumford on the melting of ice, and the propagation of heat through liquids, will oblige Mr de Lue to change the tasks of the ingredients, both of vapour and of electric stud. Water, and not fire, seems to be the carrier or deferent fluid; and we think that Franklin and Æpinus have made it highly probable that elec-

tricity, and not air, is the carrier.

We have also great difficulty in conceiving (indeed we cannot conceive) how the deferent fluid, from which the electric matter has been detached by its superior affinity with the fide A, can overcome the fame superior affinity of the electric matter with the fide B (A), and carry it off; how the deferent fluid penetrates the non-conducting pane, in order to carry off the electric matter in the form of fluid; and how it cannot do this, except by means of a conducting canal, into which it is expressly faid that it does not penetrate. It must not be said that it runs along the furface of this canal: for the imallest wire will be a sufficient conductor, covered a foot thick with fealing wax. This indeed, according to Mr de Luc, allows the deferent fluid to pass; but it must also, according to him, strain it pretty clear of all electric matter. For we cannot help thinking, that the process (although purely ideal) has a closer resemblance to what we should observe in a stream of muddy water poured on a strainer, both sides of which are previously foul. If we were disposed to amuse ourselves with a figurative hypothesis, we could give one on the principle of filtration that is very pretty, and pat to the purpole, of glass coated, and charged and discharged by conducting canals.

With respect to the suggestion of this theory by Volta's theory of electric influences, and the ignorance of naturalists before that time of the true state of things, we must observe, that Mr Russel proposed the same analogy to the consideration of his hearers many years before; and it was very generally known. The electric influences had been fully detailed by Æpinus and Wilcke in 1759, and applied with peculiar address and force of evidence by Mr Cavendish before 1771; and they were described nearly in the same way by Lane,

Lichtenberg, and others.

And with respect to Mr Volta's general principle, which Mr de Lue prizes so highly, and by which he explains every thing, we must observe, that it is not true as a phenomenon in electricity; but, on the contrary, the positive state of a body is rendered stronger, or more remarkable, by inducing the negative state on a neighbouring body. See no 52. and 66. Mr Volta was missed by the appearances of the electrophorus, which had engaged all his attention, and modelled all his notions on these subjects.

⁽A) We may here ask, How comes there to be such a quantity of electric matter already lodged in B?—Is

His observations had been confined to disks; and though these are excellent instruments for producing very senfible effects, they are quite unfit for examining the general nature of electric influences. Even without much knowledge of dynamics, a person must perceive that the action of their different parts on the electrometer may be very different, by reason of their different pofitions and distances from it. Besides, the electrometers of the apparatus described by Mr de Luc in sect. 440. &c. did not indicate the real condition of the disks to which they were attached, but the condition of the remote ends of overcharged conductors of confiderable length. Therefore, although all the electrometers fell lower when the other group of disks was brought near, the positive state of the nearest disk was greatly augmented. The most unexceptionable apparatus for this purpose would be a row of polished balls on insulating stands, placed in contact, the whole charged positive; and when another such group, or a long body, is brought near, let the balls be separated at once, and examined apart by a very small electrometer, made in the form of our figure 8. We prefume to fay that, if the other group is properly managed, and made to communicate thoroughly with the ground, the positive electricity of the balls nearest to it will be found greatly augmented, and that every one of them will be found in that precise state of electrification that is pointed out by the Æpinian theory. Mr de Luc has made and narrated the experiments with the disks, and the curious figures observed by Lichtenbergh, with great judgment and fidelity; and they are claffical and valuable experiments for the examination of the theory. We may here mention a very neat way of executing the apparatus of balls, which was practifed by a young friend, who was fo kind as to make the experiments for us, when our thoughts were turned to Mr de Luc's theory. Each ball was mounted on a slender glass rod varnished. The lower end of the stalk was fixed in a little block of wood which had a square hole through it, by which it flided fleadily along a horizontal bar of mahogany, supported at the ends about an inch from the table. The balls were made to separate at once, and equally, from each other, by a chequer-jointed frame, fuch as is feen in the toyshops, carrying a company of foot foldiers, who open and close their ranks and files by pulling or pushing the ends of the frame. Taking out the pins of the middle joints of this checquered frame-work, and widening the holes for receiving the glass stalks, it is plain that all the balls will feparate at once, in the very thate of electricity in which they were when in the neighbourhood of the non-infulated group. This apparatus confilted of fix balls. We found the ball next the other group much more strongly positive than be-fore bringing that group near; and it was generally the third ball which seemed equally electric in both situations. We added nine balls more, connecting the whole by a fimilar contrivance; and found it a most instructive apparatus for the theory of the distribution of the electric fluid. We wish that it had occurred to ws when the no 62, &c. were under confideration.

With respect to the condition in which the electric matter is said to be lodged in the side A of the coated pane, where Mr de Luc says that it is fixed, engourdi, in the non-condusting surface (which condition Mr de Luc considers as characteristic of such substances), we Suppl. Vol. 1. Part II.
